Language standardization gives privilege, authority, and legitimacy to a particular language variety, and thus creates a hierarchy in which 'nonstandard' varieties, whether they are characterized as accents, dialects, or other languages, are marginalized. Such a linguistic hierarchy is often hegemonic in the sense that it is simply taken for granted by speakers. Even in a society where a multicultural, multiethnic, and multilingual ideal is officially celebrated and advocated, the standardness of language is tacitly assumed and naturalized in such a way that it is associated with moral superiority, class mobility, and 'culture.' For example, Silverstein (1996) calls the United States "a culture of monoglot standardization," in which the function of language is reduced to the 'referential,' a one-to-one correspondence between a word and its meaning – like a dictionary. The fact that language standardization is a sociopolitical process is thus suppressed, and the process of standardization is presented as if it were the consequence of some sort of natural selection in which language achieves the perfect 'fit,' or one-to-one correspondence between the word and its meaning, as more and more speakers agree upon a particular word–meaning correspondence and use it in communicating with each other. The monoglot ideology rationalizes itself as a free market: it takes on a life of its own, operating beyond any one actor's deliberate control. Understanding language standardization as a 'natural' process that goes beyond human control also justifies the existence of hegemonic social institutions such as education, the media, and even academic linguistics, as if they existed simply as transparent transmitters of the 'natural' course of linguistic events, rather than creating and enforcing the standard.

One can recognize a complicit relationship between the monoglot ideal and social reproduction. The hegemony of the monoglot ideology within the nation-state depends upon the degree to which what the French sociologist Pierre Bourdieu (1991) called a 'linguistic market' is nationally integrated. Just like a commodity market, the value of a particular way of speaking is set according to the law of price in that particular market. Bourdieu saw language use as an embodied practice that is habitually acquired over a long period of time ('linguistic habitus'), in a particular social field. Some linguistic habitus maintain or expand their normative value in multiple fields and others lose value. For example, working-class language variations, when used outside of working-class neighborhoods in certain fields such as higher education and the white-collar workplace, would be devalued. This devaluation is a form of symbolic violence in Bourdieu's terms, by which nonstandard speakers are subjected to systematic subordination, with attendant disadvantages in social, political, and economic competition. Critically, however, the subordinated, whose language use is devalued, themselves misrecognize that the standard form, which is an arbitrary effect of power, is somehow inherently superior to theirs, and its legitimacy is voluntarily endorsed even by those most harmed by it. The standard is also reified in the form of a commodity, so that those who do not speak the standard form are made to believe that they can 'own' it through judicious enterprise. The concept of the linguistic market explains how the dominant group achieves social, particularly class, reproduction: since the linguistic habitus of the dominant group is the standard language in major national institutions such as education, government, media, law, and so on, they enjoy a monopoly on linguistic capital, or at least better access and control, by which they further maintain their social dominance through the social and business advantages accruing to their linguistic capital. The monoglot ideal thus serves to reproduce their dominance as they control formal institutions.

Standardization and Contestation

Bourdieu's model has been questioned, however, by Woolard (1985), who asked if it is ever possible for a

linguistic market to be fully integrated nationally. She argued that our ability to understand linguistic hegemony and social reproduction suffers if we limit ourselves, as Bourdieu does, to the level of formal institutions such as public education. Her ethnographic case in point is the bilingual situation in Catalonia, Spain, where "Castilian (called 'Spanish' in Anglophone usage)," the state's official language, coexists with Catalan (Catalan–Valencian–Balear), a regional language. In spite of Castilian's official language status, it is not necessarily completely hegemonic. Catalan is, in fact, positively valued, associated with status, self-confidence, intelligence, and culture by both Catalan and Castilian speakers. Such a valorization of Catalan has to do with the dominant economic status of the Catalan bourgeoisie. While Catalan is not the language of authority in formal institutions, such as the schools and government offices, it has a clear legitimacy and prestige within civil society and in less formal settings. In these settings, people engage in face-to-face encounters with Catalan speakers who are a middle-class presence as managers, residents of 'better' neighborhoods, and small business owners. Thus, the 'national' linguistic market may not reach much of daily life in localities where alternative markets may actually work at odds with the 'price setting' in the national market and potentially undermine the claimed national linguistic hegemony.

Alternative linguistic markets also often entail acts of resistance and contestation. The official language may well be a highly visible target when a subnational group identifies it as the symbol of state's domination and control by what is seen as an alien group in power. Resistance may then take the form of claims of cultural and political sovereignty against the state by means of reviving the subnational group's 'own' language and establishing its linguistic identity. The Basque separatists in Spain are a case in point (Urla, 1988). Although Basques in the autonomous Basque country are legally accorded the right to learn and use Euskara (Basque), Castilian is still, just as in Catalonia, the state's official language even within the Basque country. Basque activists, not surprisingly, promote the use of Euskara in public domains and its official use in formal institutions.

Strategies of Minority Language Groups

As Urla pointed out, however, the Basque linguistic nationalist movement can be better understood based not on notions of primordial essence in opposition to state authority so much as on a notion of modernization. Rational and scientific management, preservation, and development of the Basque language are central in this identity movement. This 'modern' strategy, by which ethnic minorities attempt to establish their linguistic – and, by extension, cultural – identity and autonomy by proving that their language is just as 'modern,' 'logical,' and 'rational' as dominant languages, has been deployed in a wide range of cultural conflicts currently observed in various parts of the world. This strategy logically entails efforts to show that there is a unity and boundedness to 'our,' which is characterized by a single standard. Thus, minority language revitalization movements often subscribe to a monoglot ideology, the same language ideology that the dominant language groups deploy to marginalize variation.

One concrete strategy of minority language revitalization is formal codification through practices of literacy, orthography, dictionary, grammar, or census. In Corsica, a region of France on a Mediterranean island, for example, Corsican speakers live in diglossia: French is used in the official and public domains, and Corsican in those of the private and the domestic. Just like Basque speakers, Corsican language planners' goal is to claim the legitimacy of Corsican as a full, autonomous language, and thus to accord it the same symbolic value as French – as the code of power and authority, to be used in the public and official domains. Language activists focus on literacy and on establishing a standardized orthographic system of Corsican. Jaffe (1996) showed how codification as a strategy to claim linguistic autonomy as an established code with certain cultural values – just like French – is both a form of resistance to the diglossic hierarchy between Corsican and French, but also complicit in that hierarchy.

It is indeed empowering to represent the language as fully coded and as holding established cultural values – solidarity and egalitarianism – unique to Corsican in opposition to French. But this strategy also backhandedly maintains the monoglot ideology that underwrites the dominant position of French: Corsicans claim their ethnolinguistic essence such as intimacy and egalitarianism **only** in opposition to the public and official function of French, continue to confine Corsican to the private and domestic realms, and also deny the vital heterogeneity within the Corsican language.

We find the same predicament and struggle over codification in minority language revitalization movements in linguistic communities around the world, including, for example, Haitian creole (Haitian Creole French) (Schieffelin and Doucet, 1994); Tolowa, a California Indian language (Collins, 1998); and Ebonics (Baugh, 2000). In the Haitian creole case, for example, the debate about which system of orthography to adopt involves a political

debate about the ethnolinguistic roots of the Haitian language. A hybrid of French and African languages, what is the 'origin' of Haitian, and, by extension, what 'people' is the postcolonial nation of Haiti built upon? The politics of language thus centers around how to codify a nation's 'own': what techniques are to be used – orthography, language education? – and what lines are to be drawn – France, Africa, a 'Black Atlantic'? Such cases all clearly demonstrate that the question of how language is to be represented is inseparable from the question of how the nation and cultural identity are represented.

Language Standardization and Transnational Political Economy

As was mentioned above, ethnolinguistic diversity within the nation-state, often accompanied by political claims to cultural autonomy, make a fully integrated **national** linguistic market untenable. But we now recognize that the politics of language is not energized only by forces contained within nation-states: the possibilities both of a hegemonic national standard language and of its contestation by local and autonomy movements are often affected by transnational language movements and cultural-linguistic 'flows.' For example, when key institutions or arrangements within the nation-state – such as public education; labor, consumer, and other markets; the bureaucracy, including regional governance – are not tightly integrated or effectively nationalized, the prestige and authority granted by the state's designated standard language(s) are not necessarily guaranteed. Such 'weak' states and 'developing economies' are, of course, commonly the product of systemic global inequality rooted in the uneven development at the heart of the capitalism as a global social formation.

In Egypt, for example, as an effect of both colonial roots and neocolonial trade, the domestic economic infrastructure has systematically relied heavily on investments and funds from the metropolitan countries. The elite classes – both native and nonnative – which dominate Egypt's political economy are educated in languages such as English, French, and Italian, and proficiency in those languages is widely recognized as linguistic capital for socioeconomic success, notwithstanding the nation's official language, Classical Arabic (Standard Arabic) (Haeri, 1997).

The case of German speakers in Transylvania, Romania, illuminates a similar point (Gal, 1987). While Romania's national language has been Romanian, it is not used in intragroup communication among German speakers. Because of their relatively privileged economic standing within the country and their economically advantageous ties to Germany, one of Europe's economic metropoles, through emigration opportunities, German as a minority language is actively maintained and accorded authority. Although the maintenance of German is in part an act of resistance to Romanian nationalism, the value of German derives also from the group's status and positioning within the broader political economy of the European Union.

Heller's (2003) ethnographic study of the French-speaking minority in Canada also showed how the transnational or global political economy shifts the value of the official language beyond the state's ability to control it. Although French is one of the two official languages in Canada, it does not enjoy the prestige that English does. This is in part due to the fact that the regional economy in francophone areas has been based traditionally on primary industry such as agriculture, fishery, forestry, mining, and industrial labor, which has suffered from continuous stagnation in the last three decades. To use Bourdieu's term, the value of French as linguistic capital within the national linguistic market, in terms of social mobility and economic gain, is lower than English, which is the language of the high-tech and financial industries. There has, however, been a shift in the way French speakers renegotiate their linguistic and cultural identity, as the regional economy has become increasingly linked with the global political economy by, particularly, the development of transnational service industries, such as offshore call centers and heritage tourism. Such service industries take advantage of French in particular and bilingual fluency in general. What defines the shifting – and, now, more positive – meaning of French does not come from the state or even the national political economy, but from the global economy. At the same time, however, as Heller pointed out, it is important to note that this 'improvement' means that francophone ethnolinguistic identity also shifts from an emblem of ethnic and cultural community to a distinct commodity for competitive sales globally.

Language Standardization in Postcolonial States

The phenomenon of language standardization takes on a different kind of complexity and politics in nation-state building among formerly colonized countries. Most of these nations were and are predominantly multiethnic and multilingual, the European colonial borders having been inserted on the basis of logics other than indigenous identities. While some sort of lingua franca, or hybrid variety, existed for interethnic communication, particularly

for trading, the notion of a standard language, or one superimposed on variations, was not necessarily available, or even conceivable, until monoglot linguistic ideology was brought by colonial rulers. The rise of nationalist movements as the predominant form taken by anticolonialism prompted native colonial elites in each colony to conceive their 'own national language' – as opposed to the colonizer's language. This was a critical step in the development of national cultures through the print media and literary arts. Upon formal independence, which came after World War II for most colonies, nation building always considered the creation of a national language as one of the pressing priorities. In many postcolonial nation-states, language standardization involves two interrelated issues. One is the question of whose language, out of multiple languages from a variety of regions and ethnic groups, should be the national language. The other concerns the question of what to do with the language of the colonial administration, in which the colonized elite classes were educated. The claim of 'national' language is deeply embedded both in the anticolonial, nationalist political consciousness, on one hand, and in the modernist aspiration to attain 'one language, one nation,' on the other.

One example can be drawn from India's postcolonial language standardization process (Washbrook, 1991; Lelyveld, 1993; Cohn, 1996). Under British colonial rule from the 18th century until 1947, India's multilingual situation (with no standard language and no systematic indigenous knowledge about the relationship between the languages) was a sign of backwardness, and was therefore to be reformed so as to establish a centralized administrative channel of communication and generally to civilize 'Indians' (a colonial category that was not coterminous with precolonial, indigenous state-imposed statuses). Based on monoglot ideology, colonial rulers produced a systematic colonial knowledge of Indian languages in the form of dictionaries, grammars, lexicographies, and linguistic manuals for colonial administrators. Philological science was also mobilized to classify the languages and to identify their prototype and the cognate relationship among them, so as to determine the basis of the standard form. All of these colonial linguistic knowledges were produced alongside censuses and agricultural, geographical, medical, and anthropological knowledges of the colonial objects.

Particularly notable was the introduction to Indian society of the notion of 'linguistic identity,' or the idea that one language corresponds to one bounded territory (and its people), and that linguistic difference constitutes ethnic difference. In other words, this new knowledge of language categories such as Hindi, Punjabi (Panjabi), and Urdu came to be the basis on which the Indian territory was divided up into mutually exclusive regions. Thus, the colonial discourse actually produced what it claimed merely to be describing: strong regionalism, a critical source of national and regional political conflict to this day. Consequently, English, which has no association with any one Indian region, paradoxically remains preferred as a means of 'national' communication by the national government.

Upon its declaration of independence from the Netherlands in 1945, the Indonesian government designated Bahasa Indonesia (or Indonesian) as its national language (Anderson, 1983; Errington, 2000; Keane, 2003). As a Malay variety, it was originally a lingua franca used by Dutch colonialists for administration, and later became both the symbol and the communicative means of the Indonesian nationalist movement in the early 20th century. But with more than 500 languages spread across 6000 inhabited islands, Indonesia is the ultimate modern, multilingual nation-state. For the majority of speakers, therefore, Bahasa Indonesia is their second language. The choice of Bahasa Indonesia as the national language was based on the fact that it is a translocal language with no concrete connection with any place or any people within Indonesia, or with the Dutch colonizers. Bahasa Indonesia symbolizes the nation's egalitarianism in a paradoxical way: it is everybody's language, accessible to anyone, and at the same time, it is nobody's (first) language, with no ethnolingusitic origin within the nation.

Democratic pluralism, often envisioned as a goal in multiethnic and multilinguistic postcolonial states, is central to the language standardization policy in Zambia, where more than 15 languages are spoken among 73 ethnic groups. As in Indonesia, the critical issue in Zambia's nation building concerned how to negotiate the political tension between the ideal of national unity and that of a national tolerance of diversity (Spitulnik, 1998). While Zambia's official language is English, ethnic languages are put on public display to demonstrate the nation's democratic pluralism. One such public space is radio broadcasting. Spitulnik described how, for example, the equal distribution of airtime to different languages is meant to be the iconic representation of democratic ethnolinguistic pluralism. At the same time, however, because of the differential economic and political status linked to languages, there inevitably exists an understood hierarchy among them. Indeed, this inequality is often reflected in radio programming, so that more prestigious or serious content may be broadcast

in a more valued language, and a less valued language may be relegated to being the medium for broadcasting more frivolous content.

Although these postcolonial sociolinguistic situations might seem extreme and unique, they attest to a general condition of language standardization in that it is never only about language, but always also about politics and identity. Beneath the standard form, there always exist competing ideas and beliefs about language, which can potentially erupt as political and cultural conflicts. Finally, these cases also highlight the importance of situating the matter of language in a broader historical as well as political-economic context.

Stang, Christian S. (b. 1900)

D Haug, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Stang was a Norwegian linguist who specialized in Baltic languages and comparative Indo-European linguistics and was professor of Slavonic languages at the University of Oslo, 1937–1970. Stang studied comparative Indo-European linguistics in Oslo and Paris, where he attended the lectures of Antoine Meillet, who would remain his scholarly model throughout his life.

Soon Stang became particularly attracted to Slavic and Baltic linguistics, and between 1923 and 1925, he made several study trips to Russia and Lithuania. In 1929, he defended his doctoral thesis *Die Sprache des litauischen Katechismus von Mažvydas* (1929), a study of the oldest extant Lithuanian text. His interest in Indo-European linguistics often led him to older stages of Balto-Slavic, but he also worked on the modern languages as in *Das Fischerlitauisch in Preussen* (1932) which he wrote together with Georg Gerullis.

His main field remained diachronic linguistics, however, and he published philological studies of the languages of particular texts such as *Die westrussische Kanzleisprache des Grossfürstentums Litauen* (1935) and *Die altrussische Urkundensprache der Stadt Polozk* (1939) as well as monographs on topics of Balto-Slavic historical linguistics such as *Das slavische und baltische Verbum* (1942) and *Slavonic accentuation* (1957). All his work on Baltic historical linguistics was summed up in his *Vergleichende Grammatik der baltischen Sprachen* (1966), which remains the fundamental work on the subject.

Stang did not limit himself to Balto-Slavic linguistics, but published comparative studies on other IE languages and treated problems of the IE proto-language itself. (Selected studies are found in Stang, 1970.) His idea that the endings of the IE perfect are closely related to those of the medium has turned out particularly influential and underlies much recent work in IE linguistics. He also published a study on the *Lexikalische Sonderübereinstimmungen zwischen dem Slavischen, Baltischen und Germanischen* (1972), where the influence of Meillet's 'étymologie–histoire des mots' can be seen.

Like the fellow Norwegian linguists of his generation, Stang was never occupied with linguistic theory and throughout his life, he remained a rather orthodox neogrammarian who sought a historical interpretation of data that he gathered not only from texts, but also from field studies. In this respect, he made a lasting contribution to the historical grammar of the Baltic languages.

States of the Glottis

J H Esling, University of Victoria, Victoria, British Columbia, Canada

© 2006 Elsevier Ltd. All rights reserved.

Historical Background

The glottis is the opening between the vocal folds in the larynx that is generally thought of as the primary valve between the lungs and the mouth; the states of the glottis are the positions generally considered to characterize the different possible shapes of this opening. In fact, there are two main valves (and a third minor valve) at work in the human larynx, and 'states of the glottis' are perhaps better thought of as 'states of the larynx.' Abercrombie (1967: 26) specifies four basic states of the glottal passage: open, in vibration, narrowed, and closed. The first two categories date back to Holder (1669) and characterize the open or abducted position of the vocal folds for 'breath,' which is akin to normal breathing, and the vibrating or adducted position of the vocal folds for the production of 'voice.' In characterizing sounds in the flow of speech, a very general parallel can be drawn between 'voiceless' flow, with the glottis in the open position of breath, and 'voiced' flow, with the glottis in the vibrating position of voice. The narrowed glottis that Abercrombie refers to is meant to account for 'whisper,' which is noisier than 'breath,' and the closed glottis refers to the state known as a 'glottal stop,' when the passage is closed, allowing no air (either breath or voiced flow) to pass through. Although states of the glottis refer specifically to postures identified within the larynx, they carry implications for physiological functions, including aspects of airflow, during speech.

In the 19th century, Alexander Melville Bell very astutely identified a point of stricture superior to the glottis. What he called the 'super-glottal passage' is open during 'breath,' as is the glottis itself, while the 'super-glottal passage' is contracted during 'whisper,' while the glottis itself remains open (Bell, 1867: 46). Recent research confirms Bell's description, identifying the laryngeal constrictor mechanism as the sphincteric aryepiglottic folds that pull the laryngeal cartilages upward and forward toward the epiglottis when fully contracted, thereby shutting off the airway completely and powerfully (Esling, 1996). This aryepiglottic laryngeal constrictor is active in the narrowing of the immediate supraglottic passage for the production of whisper. A related inferior and less extreme contraction of the constrictor musculature appears to be responsible for arresting airflow through the glottis when the adducted vocal folds (with, in Bell's terms, "conjoined edges") are pressed upon by the immediately superior ventricular folds to produce glottal stop (Esling and Harris, 2003, 2005).

It is well known in the study of the voice that changing pitch (the vibrating frequency of the vocal folds) changes in various ways the perceived quality of the sound that results (*see* **Voice Quality**). The high-pitched version of the neutral modality of voicing has been called 'falsetto' since the writing of Sweet (1877: 3, 1890), who characterized it as the "shrillest form" of the head register, using the terminology 'chest' and 'head' voice proposed by Garcia (1855, 1856), which is still often used in descriptions of the singing voice throughout the 20th century. The term for chest voice proposed by Hollien (1972: 320) and adopted by Laver (1980: 95) is 'modal voice.' Falsetto is a glottal phenomenon, resulting from the adduction of the vocal folds to produce voice but with the addition of enough tilting of the laryngeal cartilages to stretch the vocal folds, making them long and thin. The frequency of vibration (perceived as pitch) is much faster in falsetto because the taut vocal folds only permit vibration along a short portion of their length. Since the vibrating mass of long thin vocal folds is different from the vibrating mass of shorter and thicker vocal folds, the quality of the sound also differs.

The basic states of the glottis defined in the 19th century, therefore, evoke three distinct laryngeal processes that can be considered essential in the physiological description of laryngeal function: glottal abduction/adduction, glottal stretching for pitch, and laryngeal constriction. Breath is an example of glottal abduction; voice and falsetto are examples of glottal adduction; and whisper and glottal stop are examples of the effects of laryngeal constriction. Whisper illustrates laryngeal constriction with glottal abduction, and glottal stop illustrates minimal inferior laryngeal constriction with glottal adduction. Beyond these basic laryngeal states, further combinations are possible, drawing on different permutations of the three principal laryngeal processes.

Elaborations on the Basic States

In contrast to breath and glottal stop, another voiceless state of the glottis can be identified that is partially open but through which no air is flowing. While the state of the glottis for voiceless aspirated oral stops and affricates (during the aspiration phase) is breath, the state of the glottis for voiceless unaspirated oral stops and affricates is a configuration

described as 'prephonation.' Prephonation, as distinct from other voiceless states of the glottis such as breath, is made with the arytenoid cartilages adducted as for modal voice, but with the vocal folds forming a narrowed convex-convex opening during which subglottal air pressure is insufficient to initiate airflow through the partially open glottis while the closure phase of oral articulatory stricture is maintained (Harris, 1999, 2001). While in some languages, word-initial vowels may typically begin with a glottal stop, in English and in Thai, word-initial vowels are usually preceded by prephonation, unless they are heavily stressed.

In addition to glottal stop, a more complete closure of the laryngeal passage is also possible. The most efficient closure of the airway in the human larynx is a complete engagement of the laryngeal constrictor mechanism, known in phonetics as an 'epiglottal stop' (Esling, 1996, 1999). This state of closure has been found to be one of the first 'sounds' that an infant articulates as it learns to control its breathing and swallowing in conjunction with early vocalizations (Esling *et al.,* 2004). Both kinds of stop are referred to as 'unphonated' (Catford, 1990), which implies that no airstream is passing through the glottis. Epiglottal stop occurs as a speech sound in some dialects of Arabic, identified by Hockett (1958: 66) as a 'pharyngeal catch'; in languages of the Caucasus such as Chechen, identified by Catford (1983: 347) as a 'pharyngealized glottal stop,' 'strong glottal stop,' or 'pharyngeal stop'; and in the Pacific Northwest languages, Salish (Carlson *et al.,* 2004) and Wakashan (Esling *et al.,* 2005).

The Nature of 'Compound' States

Bell recognized that aspects of the basic states could be combined. He defined a compound phonatory category of 'whisper and voice heard simultaneously,' which he called 'vocal murmur' (1867: 46). This is the state of 'whispery voice,' which continues to be called murmur in many phonetic descriptions. It combines vocal fold vibrations at the front part of glottis with airflow through the open back part of the glottis, channeled through a variably constricted laryngeal sphincter above the glottis. A parallel compound category, 'breathy voice,' involves no laryngeal sphinctering but otherwise has the same voiced (vibrating) and friction (airflow) components as in whispery voice. Being less impeded laryngeally, breathy voice therefore has a higher rate of airflow (Catford, 1964: 32; 1977: 101; *see* **Phonetic Processes in Discourse**).

To account for the low end of the pitch range, where vocal fold vibrations are slow and sound like individual pulses, modal voice gives way to 'creaky voice.' It is one aspect of what is often called a 'deep' or 'rich, bass' voice. It could be said that the two components combining to produce the quality of creaky voice are voicing at the glottis and constriction at the laryngeal sphincter. Since whisperiness and creakiness are both constricted states, they naturally combine with another constricted laryngeal configuration – harshness – when used as labels for describing voices (*see* **Voice Quality**). Constricted states such as creaky voice (or harshness) are phonated states that are very close to becoming unphonated, i.e., closing off the airway as in a moderate glottal stop or in a full epiglottal stop.

Based on the description of the laryngeal constrictor, there is also a rationale for treating harshness, usually described as a phonation type, as a laryngeal state and for relating different qualities of harshness to glottal pitch (Esling and Harris, 2003, 2005). The three basic laryngeal processes highlighted above – glottal abduction/adduction, glottal stretching for pitch, and laryngeal constriction – can be thought of as combining to produce a set of qualities usually known as varieties of 'harsh voice' but occurring in three distinct pitch ranges. In this way, laryngeal constriction combines with glottal stretching to produce a new set of constricted counterparts to creaky voice, modal voice, and falsetto: low-pitched harsh voice (with aryepiglottic trilling), mid-pitch harsh voice, and high-pitched harsh voice (with extreme degrees of compression in both the postero-anterior constrictor dimension over the glottis and the antero-posterior stretching dimension at the glottis).

All three types are assumed to be voiced (with glottal adduction). The low-frequency component that enhances creaky voice at the low-pitched end of the harsh range is attributed to the vibration of the aryepiglottic folds (which define the laryngeal sphincter over the top of the glottis). Although creak is already low-pitched (typically around 80 to 100 Hz), aryepiglottic fold vibration is detected at about half that number of periods: around 50 Hz. This mode of laryngeal activity has been identified as a contrastive tonal register in the Bai language of China, in opposition to breathy voice, modal voice, and harsh voice without aryepiglottic trilling (Esling and Edmondson, 2002). It is entirely possible that glottal phonation in this mode is creaky, while aryepiglottic fold vibration contributes the impression of harshness. It is significant to note that the location of aryepiglottic stricture is the same place of articulation that accounts for sounds that are labeled 'pharyngeal' or 'epiglottal' in phonetics. Thus, aryepiglottic trilling could also be called a 'pharyngeal trill' articulatorily, in the same way that an epiglottal stop had been referred to earlier by Catford as a pharyngeal stop.

Harsh voice at mid pitch range is aperiodic and may involve an increase in airflow pressure to counteract the tightness imposed by the laryngeal valve. In Laver's account (1980: 129), the most commonly reported correlate of harshness is 'laryngeal tension.' As pitch increases, while maintaining at least as much contraction of the laryngeal constrictor as for harsh voice at mid pitch, the impression of tension becomes extreme, and the state of the glottis that results – high-pitched harsh voice – resembles glottal stop in configuration, except that phonation continues (whereas for glottal stop, phonation ceases). The auditory quality that this combination of tightening mechanisms generates had been referred to in many earlier formulations as 'ventricular voice' (see Laver, 1980), but it is the aryepiglottic folds rather than the ventricular folds (false vocal folds) that are critical to the point of stricture. In this state, the two opposing forces of laryngeal tension – aryepiglottic sphincteric and glottal stretching – act simultaneously to produce the most strained phonation type possible without actually stopping vibration at the glottis. This state of the glottis is falsetto-like in its characteristic high pitch, but the irregular signal that it generates (auditorily tense, i.e., harsh) is related to the sphincteric constriction in the aryepiglottic structures immediately superior to the glottis.

The Study of Linguistic Variation

The quantitative study of linguistic variation originated in the studies conducted by William Labov in New York 1960s and 1970s (e.g., Labov, 1966, 1972). This approach to the study of language in its social context was subsequently extended to a wide variety of languages in communities around the world. The main ideas are that an understanding of language requires an understanding of variable as well as categorical processes and that most of the variation that we witness at all levels of language is systematically constrained by multiple linguistic and social factors that reflect underlying grammatical systems and that both reflect and contribute to the social organization of the communities to which speakers belong. This article focuses on methods of statistical analysis commonly used in the study of linguistic variation, with emphasis on variable rule, or VARBRUL, analysis, a specialized application of the statistical procedure known as logistic regression. Alternatives to VARBRUL, such as the logistic regression modules as implemented in commercial statistical packages, are also briefly considered.

Multivariate Analysis with VARBRUL

Modeling linguistic variation can be carried out by a number of commercial statistical software packages, usually under the name of logistic regression. However, the programs known as VARBRUL have been used most extensively in sociolinguistics, because they have been deliberately designed to handle the kind of data obtained in studies of variation. In particular, VARBRUL allows the researcher to model simultaneously the effects of the multiple factors that may condition a speaker's choice of one or another variant and to determine which factors have a statistically significant effect on that choice and which do not. VARBRUL also provides heuristic tools that enable the researcher to modify hypotheses and reanalyze the data easily to compare alternative models. The statistical bases for the VARBRUL programs are set out in Rouseau and Sankoff (1978) and Sankoff (1988b) and the mathematical basis of logistic regression is explained in detail in Hosmer and Lemeshow (1989). The procedures for using the software are covered in detail in Young and Bayley (1996) and in the documentation that accompanies the programs. The two most widely available versions are GoldVarb for the Macintosh (Rand and Sankoff, 1991) and for Windows (Lawrence, Robinson, and Tagliamonte, 2001).

A full explanation of the steps involved in carrying out a multivariate analysis with VARBRUL is beyond the scope of this article. Hence, the discussion will be limited to addressing several questions that arise in any study, including defining the envelope of variation, testing for significance, interpreting the results, and dealing with the limitations inherent in the program. Readers who wish to pursue the topic in greater depth should consult the extensive literature on variable rule analysis and use of the VARBRUL programs (e.g., Bayley, 2002; Cedergren and Sankoff, 1974; Guy, 1993; Mendoza-Denton, Hay, and Jannedy, 2003; Paolillo, 2002; Rousseau and Sankoff, 1978; Sankoff, 1988b; Young and Bayley, 1996).

Defining the Variable and the Envelope of Variation

The first step in conducting a VARBRUL analysis is to define the variable, including the envelope of variation. That is, what forms count as instances of the variable under investigation and what forms should be excluded from analysis? Are the forms that vary indeed two ways of saying the same thing and are the forms actually variable in all of the environments considered? In many studies, particularly studies of phonological variation, defining the envelope of variation is not a problem. For example, *working* and *workin'* clearly have the same referential meaning, as do *west side* and *wes' side*. Moreover, a considerable body of research has shown that alveolarization of /ŋ/ and consonant cluster reduction, or -t,d deletion, are widespread across English dialects (Labov,

The Study of Linguistic Variation

The quantitative study of linguistic variation originated in the studies conducted by William Labov in New York 1960s and 1970s (e.g., Labov, 1966, 1972). This approach to the study of language in its social context was subsequently extended to a wide variety of languages in communities around the world. The main ideas are that an understanding of language requires an understanding of variable as well as categorical processes and that most of the variation that we witness at all levels of language is systematically constrained by multiple linguistic and social factors that reflect underlying grammatical systems and that both reflect and contribute to the social organization of the communities to which speakers belong. This article focuses on methods of statistical analysis commonly used in the study of linguistic variation, with emphasis on variable rule, or VARBRUL, analysis, a specialized application of the statistical procedure known as logistic regression. Alternatives to VARBRUL, such as the logistic regression modules as implemented in commercial statistical packages, are also briefly considered.

Multivariate Analysis with VARBRUL

Modeling linguistic variation can be carried out by a number of commercial statistical software packages, usually under the name of logistic regression. However, the programs known as VARBRUL have been used most extensively in sociolinguistics, because they have been deliberately designed to handle the kind of data obtained in studies of variation. In particular, VARBRUL allows the researcher to model simultaneously the effects of the multiple factors that may condition a speaker's choice of one or another variant and to determine which factors have a statistically significant effect on that choice and which do not. VARBRUL also provides heuristic tools that enable the researcher to modify hypotheses and reanalyze the data easily to compare alternative models. The statistical bases for the VARBRUL programs are set out in Rouseau and Sankoff (1978) and Sankoff (1988b) and the mathematical basis of logistic regression is explained in detail in Hosmer and Lemeshow (1989). The procedures for using the software are covered in detail in Young and Bayley (1996) and in the documentation that accompanies the programs. The two most widely available versions are GoldVarb for the Macintosh (Rand and Sankoff, 1991) and for Windows (Lawrence, Robinson, and Tagliamonte, 2001).

A full explanation of the steps involved in carrying out a multivariate analysis with VARBRUL is beyond the scope of this article. Hence, the discussion will be limited to addressing several questions that arise in any study, including defining the envelope of variation, testing for significance, interpreting the results, and dealing with the limitations inherent in the program. Readers who wish to pursue the topic in greater depth should consult the extensive literature on variable rule analysis and use of the VARBRUL programs (e.g., Bayley, 2002; Cedergren and Sankoff, 1974; Guy, 1993; Mendoza-Denton, Hay, and Jannedy, 2003; Paolillo, 2002; Rousseau and Sankoff, 1978; Sankoff, 1988b; Young and Bayley, 1996).

Defining the Variable and the Envelope of Variation

The first step in conducting a VARBRUL analysis is to define the variable, including the envelope of variation. That is, what forms count as instances of the variable under investigation and what forms should be excluded from analysis? Are the forms that vary indeed two ways of saying the same thing and are the forms actually variable in all of the environments considered? In many studies, particularly studies of phonological variation, defining the envelope of variation is not a problem. For example, *working* and *workin'* clearly have the same referential meaning, as do *west side* and *wes' side*. Moreover, a considerable body of research has shown that alveolarization of /ŋ/ and consonant cluster reduction, or -t,d deletion, are widespread across English dialects (Labov,

1989). However, it becomes less obvious that variable forms meet the criterion of being two ways of saying the same thing at higher levels of linguistic structure. VARBRUL has been used to analyze variation in syntax, discourse, and code-switching. However, the use of VARBRUL analysis for modeling variation in syntax in particular resulted in considerable controversy. Indeed, the problem of defining what counts as an instance of the variable may affect the study of even such frequently examined variables as the alternation between null and overt subject pronouns in languages such as Spanish, e.g.,

(1) Yo/Ø jugaba fútbol.
'I used to play soccer.'

Matos Amaral and Schwenter (2003) examined the treatment of subject personal pronouns in contrastive contexts, as in the following example from Cameron (1992), where the subject pronoun *yo* 'I' is obligatory:

(2) Ella siempre quirere ir al cine. Yo preferiría estar en casa.
'She always wants to go to the movies. I would prefer to stay home.'

However, as Matos Amaral and Schwenter point out, placement of the adverb *honestemente* 'honestly' before *yo* results in a context where both the overt and the null options are possible:

(3) Ella siempre quirere ir al cine. Honestemente yo/Ø* preferiría estar en casa.
'She always wants to go to the movies. Honestly, I would prefer to stay home.'

Matos Amaral and Schwenter observe that the majority of variationist studies have excluded contrastive contexts (or a subset thereof) from the envelope of variation on the grounds that subject pronouns are obligatory in such contexts (e.g., Bayley and Pease-Alvarez, 1997; Cameron, 1992; Silva-Corvalán, 1994). A number of other studies, however, have included contrastive contexts (e.g., Enríquez, 1984). A discussion of the contexts in which null pronouns are licensed in Spanish is beyond the scope of this article. Nevertheless, questions such as those raised by Matos Amaral and Schwenter have clear implications for quantitative analysis because the results will be affected if we exclude tokens in a context where a variant may occur, even if it does so only rarely.

Identifying Potential Constraints on Variation

The second issue concerns specifying the factors that may influence a language user's choice among variants. In general, it is best to code broadly, provided that each factor group is based on a well-motivated hypothesis. Lucas (1995), for example, investigated the potential effects of eight separate factor groups on the choice of a variant of the sign DEAF in American Sign Language (ASL). As it turned out, most of these groups proved not to be statistically significant. However, the labor of coding for many factors was not in vain. The study demonstrated that earlier beliefs that variation in the form of DEAF is influenced primarily by the location of the preceding sign, a phonological constraint, were at best incomplete. Lucas also demonstrated the previously unsuspected influence on the choice of variant of the grammatical category to which DEAF belongs, a finding that was subsequently confirmed in a large-scale study (Lucas, Bayley & Valli, 2001).

Performing VARBRUL Analysis

Once coding is complete and the data are entered into the program, VARBRUL estimates the factor values (or probabilities) for each contextual factor specified (e.g., the phonetic features of the following environment or the social class to which a speaker belongs). This is done by combining the input probability (p_0, the likelihood that the 'rule' will apply regardless of the presence or absence of any other factor in the environment) with the applicable factor weights from each of the factors in the model (p_1, p_2, ..., p_n), according to the formula:

$$p = \frac{p_0 \times \ldots \times p_n}{[p_0 \times \ldots \times p_n] + [(1 - p_0) \times \ldots \times (1 - p_n)]} \quad (1)$$

The program provides a numerical measure of the strength or influence of each factor, relative to other factors in the same group, on the occurrence of the linguistic variable under investigation. Values range between 0 and 1.00. A value, or weight, between 0.50 and 1.00 indicates that the factor favors use of a variant relative to other factors in the same group. For example, in a recent study of contact between Spanish dialects in the United States, Vélez-Salas *et al.* (2004) investigated the alternation between overt and null pronouns in the Spanish of Puerto Ricans living in San Antonio, Texas, a city where the overwhelming number of Spanish speakers is of Mexican origin. Vélez-Salas *et al.* selected the variable because Caribbean and Mexican Spanish dialects differ markedly the relative frequency of overt pronoun use. In Puerto Rican Spanish, as in other Caribbean Spanish dialects, overt subject pronouns are frequent; in Mexican Spanish, overt subject pronouns are used much more infrequently. Vélez-Salas *et al.* hypothesized that San Antonio Puerto Ricans with extensive Spanish-speaking social and professional

Table 1 The effect of coreference and verbal ambiguity on the use of overt subject personal pronouns by Puerto Rican Spanish speakers in San Antonio, Texas

Factor group	*Factor*	*N*	*VARBRUL Weight*
Coreference	Switch	1654	0.61
	Same	2265	0.42
Ambiguity of the verb form	Ambiguous	646	0.55
	Nonambiguous	3273	0.49
Total/Input		3919	0.36

networks in the local Mexican-background majority community would use fewer overt pronouns than speakers whose social and professional networks consisted primarily of other Puerto Ricans or English-speakers. They also hypothesized that the main linguistic constraints on the use of subject pronouns would operate in much the same way as they have been shown to operate in other communities.

Vélez-Salas *et al.* (2004) coded nearly 4000 tokens for a wide range of factors, including whether a token was the same or different from the subject of the preceding tensed verb and whether the subject was uniquely encoded in the verb form or whether it was potentially ambiguous, e.g., tenía 'I or s/he had'. The researchers hypothesized that, as in other Spanish dialects, the speakers in this study would be more likely to use an overt pronoun when there was a change from the preceding subject than when subject continuity was maintained. They also hypothesized that speakers would be more likely to use an overt pronominal subject in cases when the person was not uniquely encoded in the verbal inflection. The results for these two factor groups are shown in Table 1.

The results of VARBRUL analysis, which show factor weights, or probabilities, of 0.61 for switch reference and 0.42 for co-reference, confirmed the hypothesis that Puerto Ricans living in San Antonio, like speakers of other Spanish dialects, are more likely to use an overt subject pronoun when there is a switch in reference. However, the results disconfirmed the hypothesis that speakers would use more overt pronouns with ambiguous than with non-ambiguous verbs. This factor group, with weights hovering around 0.50 (0.55 for ambiguous verbs and 0.49 for nonambiguous verbs), failed to reach statistical significance.

In addition to calculating values or weights for each factor, VARBRUL calculates the input probability, or corrected mean, which, as noted above, is the overall likelihood that speakers will choose the variant selected as the application value (the value that counts as an application of the 'rule' being investigated). In Vélez-Salas *et al.*'s study, the input probability was 0.36, indicating that these speakers were likely to use an overt pronoun somewhat more often than one third of the time, regardless of the presence or absence of any other factor in the environment.

Measures of Goodness of Fit

The program also provides several measures of goodness of fit between the model and the data. These include the total chi-square, the chi-square per cell, and the log likelihood. The total chi-square measures the degree of interaction among factors from different factor groups. The chi-square per cell figure is simply the total chi-square divided by the number of cells. The lower the chi-square per cell figure, the less likely there is to be interaction between factor groups. As a general rule, a chi-square per cell figure of greater than 1.5 suggests that there may be an interaction between two or more factor groups. For example, in many societies, ethnicity and social class are closely associated. In such cases, it may be necessary to recode the data to remove the interaction (for details on recoding, see Young and Bayley, 1996: 292). Thus, rather than have separate factor groups for ethnicity and social class, it may be better to combine them. For example, two binary factor groups for African-American and Euro-American and for working- and middle-class speakers might be combined to form a single factor group consisting of African-American working class, African-American middle class, Euro-American working class, and Euro-American middle class. Finally, VARBRUL provides the log likelihood statistic, also a measure of goodness-of-fit. Figures closer to zero represent better models than log likelihoods further removed from zero (see Young and Bayley, 1996: 272–273).

Significance Testing with VARBRUL

The factor values and input probability reported in a VARBRUL run provide useful information. They are not sufficient, however, to confirm or disconfirm the hypotheses that led to the inclusion of the factors in original model of variation. The goal of studies of sociolinguistic variation, as in any scientific endeavor, is to develop the most parsimonious model that still accounts for the data. To achieve this goal, we need to test whether the results are statistically significant or whether they might be due to chance. In VARBRUL analysis, achieving the most parsimonious model involves testing whether entire factor groups significantly contribute to the overall goodness-of-fit of the model and testing whether factors within groups differ significantly from one another. Naturally, factors should only be combined where there is linguistic

or social justification for doing so. Guy (1980), for example, in a study of -t,d deletion, found that the VARBRUL weights for regular past tense verbs and past participles did not differ significantly from one another. He combined these forms on the basis of their common underlying morphological structure. It would have made little sense, however, to combine following consonants and vowels, for example, which not only contrast phonologically but have been found in other studies to differ significantly in their effect on deletion.

VARBRUL provides a means of testing whether factor groups contribute significantly to the model of variation by means of a *step-up/step-down analysis*. This involves performing a run with only one factor group and then adding each of the other factor groups to the analysis, one at a time, until all factor groups are included. When the full model with all factor groups is reached, VARBRUL then removes one factor group at a time until only one remains. During each individual run, the factor weights and the log-likelihood are calculated. At the end of the analysis, the program outputs a file with the details of each run and an indication of the best stepping-up run and the best stepping-down run. The factor groups included in the best stepping-up and stepping-down runs should be the same. These are the factor groups that are significant at or above the $p < 0.05$ level (the default significance level in VARBRUL). That is, the odds are no better than 1 in 20 that the factor group is question is not significant. Factor groups that are not included in these runs do not contribute significantly to the variation. The factor weights calculated during these runs are used to report the results of the study.

In addition to testing the significance of factor groups, it is also necessary to test whether individual factors within groups differ significantly from one another. This calculation is done by comparing the log likelihoods of two VARBRUL runs, one with the factor coded as in the original coding scheme, and one with a recode in which the factor is eliminated or collapsed with another factor. The following test is used in order to determine whether the difference between the VARBRUL weights is significant:

$$\chi^2_{\nu\alpha} \approx -2 \times (\text{log likelihood}_1 - \text{log likelihood}_2) \qquad (2)$$

That is, twice the difference in the log likelihoods of the separate analyses performed (1) with and (2) without the factor in question asymptotically approximates a chi-square distribution where ν is the number of degrees of freedom and α is the probability that the effect attributed to the factor in question is greater than would be expected by chance. The degrees of freedom used in calculating the above chi-square statistic are the difference between the degrees of freedom in the two runs. If only one factor is eliminated, there will only be a single degree of freedom used in testing for the significance of that factor.

VARBRUL: Advantages and Limitations

In contrast to the situation in the 1970s when VARBRUL was developed, procedures for doing logistic regression are now widely available. Nevertheless, many, if not most researchers in sociolinguistic variation have continued to use VARBRUL because the program offers a number of advantages. Perhaps most important, in VARBRUL recoding is relatively easy to accomplish. Thus, the statistical model of variation can be repeatedly refined to achieve the most parsimonious explanation and to eliminate any factors or entire groups that do not significantly affect variation. Second, VARBRUL reports results in a manner that is easily interpretable. As shown above, in a binomial analysis, factor weights (or probabilities) between 0 and 0.5 are said to disfavor use of the variant of the dependent variable selected as the application value. Factor weights between 0.5 and 1.0 are said to favor the use of the variant selected as the application value. In contrast, in the logistic regression routines in commonly used commercial software packages such as SPSS, results are given in the form of regression coefficients. Regression coefficients given in SPSS may be converted into probabilities by first calculating the predicted logits and then calculating the probabilities using the logistic function (Rietveld and van Hout, 1993: 332–333). Most variationists, however, are more accustomed to interpreting VARBRUL weights. Finally, cost is also a factor. In contrast to commercial statistical programs, current versions of VARBRUL are available at no cost.

Although VARBRUL offers a number of advantages, it also has serious limitations. First, although it is possible to test for interactions among the many factors that may potentially constrain a speaker's choice of a linguistic variant, unlike the logistic regression procedure in SPSS and other commercial software packages, the program does not do so automatically. Thus, VARBRUL is not necessarily the most efficient tool if interaction is likely to be a main focus of the study, although Sigley (2003) provides a guide to testing interactions with GoldVarb. Second, VARBRUL is best suited for analysis of nominal variables, e.g., presence or absence of a final consonant or a subject personal pronoun. However, many linguistic variables of interest are not nominal, but continuous. For example, Mendoza-Denton *et al.* (2003) examined monophthongization of /ay/ in the speech of television talk show host Oprah Winfrey. The researchers were able to achieve a high level of

inter-rater reliability and they confirmed their auditory analysis with acoustic verification. Nevertheless, they observed that the requirement of VARBRUL that variants be treated as discrete presents a problem when dealing with continuous phonetic phenomena such as vowel variation (Mendoza-Denton *et al.*, 2003: 114–115). Third, like the dependent variable, the factors in a VARBRUL analysis must have discrete values. This requirement poses a particular problem for studies of language development and language change where time is a factor.

VARBRUL and Other Implementations of Logistic Regression

In recent years, a number of researchers have used the logistic regression modules in commercially available statistical packages to overcome some of the limitations of VARBRUL. Young and Yandell (1999), for example, compare results obtained from a general logistic regression model and from VARBRUL. The comparison was undertaken in response to Saito's (1999) critique of Young's (1991) original VARBRUL analysis of -s plural marking by Chinese speakers of L2 English. Saito criticized Young for grouping speakers together by proficiency level rather than considering them individually and for failing to test for possible interactions between proficiency and the preceding segment effect. In the original study, Young (1991) found that proficiency level was statistically significant when all of the data were run together, with high proficiency learners more likely to mark -s plurals than low proficiency learners. He subsequently ran two separate analyses by proficiency level and found that the preceding segment, animacy, and definiteness affected high and low proficiency learners differently.

Young and Yandell reanalyzed Young's original data with the GENMOD procedure in the SAS statistical package (SAS Institute, 1996). The results of the reanalysis were comparable to the original analysis. Both the original VARBRUL analysis and the GENMOD analysis showed that proficiency, noun position, syntactic function, preceding and following segments, and redundancy significantly affected speakers' use of plural -s. In addition, the GENMOD analysis showed significant interactions between proficiency and definiteness, animacy, and the preceding segment.

As we see in Table 2, both VARBRUL and GENMOD show that redundant plural marking in the NP favors -s plural marking for speakers at all levels of English proficiency, as do prenominal modifiers. When all speakers are included in the analysis, following vowels favor -s plural marking. However, this is a rather weak constraint, as indicated by the fact that it failed to reach statistical significance when separate analyses were run by proficiency level. Table 2 also allows us to compare the interactions found in the GENMOD analysis with the results of the separate VARBRUL analyses by proficiency level. For example, in the GENMOD analysis, proficiency by animacy is significant because, as revealed in the VARBRUL analyses by proficiency level, the animacy of the NP affects high and low proficiency speakers differently. For high proficiency speakers, animate NPs favor -s plural marking. For low proficiency speakers, animate NPs disfavor plural marking.

Conclusions

As a result of its ability to handle multiple factors and highly unequal cell sizes, VARBRUL has proven to be extremely useful for analyzing variable sociolinguistic data collected in a wide variety of contexts. Moreover, as shown in the example from Young and Yandell (1999), the results of VARBRUL analysis and the results obtained with the logistic regression module in a commercially available statistical package are comparable. As discussed above, however, VARBRUL has a number of limitations that make in unsuitable for certain types of studies. Among the most potentially problematic limitations is the relative difficulty of testing for potential interactions, which, although most common between social factors, may occur between linguistic factors even in studies of such well-documented variables as consonant cluster reduction (Sigley, 2003). Also, as noted above, VARBRUL is well suited for the study of nominal variables, but it is not suitable for the study of continuous variables such as differences in formant values of vowels in two linguistic environments, or with different speakers as in Mendoza-Denton *et al.* (2003). In such a case, a comparison of means by a simple t-test would be preferable, while in more complicated designs, ANOVA (analysis of variance) would be the appropriate choice (see Reitveld and van Hout, 1993, for details of these tests).

Finally, there is the question of sampling (Sankoff, 1988a). Although early studies of sociolinguistic variation, such as Labov's (1966) study of the Lower East Side in Manhattan, followed rigorous random sampling procedures, representative sampling seems to be less of a concern in many more recent studies. Rather, quota sampling, where the researcher recruits speakers who represent the different social categories of interest, is much more common. Problems can arise, however, if the criteria for inclusion in particular categories are not sufficiently clear. Lucas *et al.*

Table 2 Comparison of VARBRUL and GENMOD results for the analysis of -s plural marking in Chinese – English interlanguage

Factor	*VARBRUL: all speakers*	*VARBRUL: low proficiency*	*VARBRUL: high proficiency*	*GENMOD*
Proficiency	High proficiency favors	na	na	na
Individual speaker	na	na	na	Significant
Redundant plural marking in NP	Redundant marking favors	Redundant marking favors	Redundant marking favors	Redundant marking favors
Syntactic function of NP	Adverbial favors	Adverbial favors	Adverbial favors	Adverbial favors
Position of noun within NP	Prenominal modifier favors	Prenominal modifier favors	Prenominal modifier favors	Prenominal modifier favors
Preceding segment	Vowels, stops, and non-sibilant fricatives favor	Vowels and stops favor	ns	Factor order is fricative > stop > vowel > nasal > sibilant > lateral
Following segment	Vowels favor	ns	ns	Vowels favor
Animacy	ns	Disfavors	Favors	ns
Definiteness	ns	ns	Disfavors	ns
Proficiency × definiteness	na	na	na	Significant
Proficiency × animacy	na	na	na	Significant
Proficiency × preceding segment	na	na	na	Significant

Notes: na, not applicable, either because the factor group was not included in the model (e.g., the interaction factor groups in the VARBRUL analyses) or because the factors in the group were dealt with elsewhere in the model (e.g., when speakers were coded as individual factors, the proficiency factor group was no longer relevant); ns, not significant at $p < .05$.
Sources: Young, 1991: 144–145; Young and Yandell, 1999.

(2001), for example, point out that some early studies of variation in ASL included both Deaf and hearing signers. Given the nature of the Deaf community in the United States, where Deaf children of Deaf parents are seen as language models, it is unclear to what extent studies that include both Deaf and hearing signers can be considered representative of ASL. Regardless of the techniques we use to test for statistical significance, our results can only be valid to the extent that participants are representative of the communities we study.

Introduction

As an empirical science, linguistics inevitably deals with real-world quantitative data from time to time. This data is sometimes bulky and unmanageable, and it is often not clear straight away what the data does and does not show. Statistics is the mathematical approach to drawing conclusions from such real-world data. This can be productively employed by a linguist who is faced with a mass of figures in order to determine what statements the figures can and cannot support.

When Does a Linguist Need to Use Statistics?

Whenever the data we are evaluating is *not* an 'all-or-nothing affair,' statistics may come into play. For example, if we were to try to establish that a particular speech sound exists in a given language, all we have to do is find one good, well-attested example of that sound occurring in order to establish the existence of that sound in the language. This is an all-or-nothing assessment.

However, if we try to establish that the same sound is *frequent* in that language, we will need to employ statistics, because relative frequency is not an all-or-nothing matter. In this case, we will need some basis of comparison on which to assert that the sound is 'frequent'; we will need a count of instances of that

Introduction

As an empirical science, linguistics inevitably deals with real-world quantitative data from time to time. This data is sometimes bulky and unmanageable, and it is often not clear straight away what the data does and does not show. Statistics is the mathematical approach to drawing conclusions from such real-world data. This can be productively employed by a linguist who is faced with a mass of figures in order to determine what statements the figures can and cannot support.

When Does a Linguist Need to Use Statistics?

Whenever the data we are evaluating is *not* an 'all-or-nothing affair,' statistics may come into play. For example, if we were to try to establish that a particular speech sound exists in a given language, all we have to do is find one good, well-attested example of that sound occurring in order to establish the existence of that sound in the language. This is an all-or-nothing assessment.

However, if we try to establish that the same sound is *frequent* in that language, we will need to employ statistics, because relative frequency is not an all-or-nothing matter. In this case, we will need some basis of comparison on which to assert that the sound is 'frequent'; we will need a count of instances of that

sound from some sample dataset of the language; and we will need some test of significance to assure ourselves that the results our statistics produce have not occurred by simple coincidence.

Any empirically based approach to linguistics which deals with large collections of data points, may have cause to employ statistical analysis. An obvious example is the large text collections employed in corpus linguistics. Other examples include the outcomes of psycholinguistic experiments, grammatical elicitation tests, or survey-based investigations.

Basic Statistical Measures

To see what kinds of basic statistical measures can be used in linguistics, let us consider an example experiment. Let us suppose that a number of speakers of English have been presented with a sentence and asked to say whether they consider it an acceptable sentence of English or not. What statistical measures might we use in a very basic analysis of this experiment?

The most basic statistical measure is a *frequency count*. In our example, we would count the number of subjects who said that the sentence is acceptable grammatically and compare this to the number of subjects who said that it is not. The frequency counts for each response are our primary statistics for this set of data.

Frequency counts are often more useful if expressed as a fraction or a percentage. For instance, knowing that 30 people in our experiment considered the sentence to be acceptable is interesting, but not terribly useful. It is much more enlightening if we say that 30 people out of 60 in the experiment consider the sentence to be acceptable, which is equal to one-half or 50%.

The percentage ('how often in a hundred') is a very common way of expressing frequencies in statistics. However, in corpus-based linguistics in particular, it is also common to express the frequency of a phenomenon in terms of *per thousand* words or even *per million words*. This means we do not have to deal with small fractions of a percent. If a particular word-form occurs on average once in a million words of running text, it is easier to say that it has a frequency of one per million words than to say it has a frequency of 0.0001%.

Percentages are of greatest use if we wish to compare two datasets or two subgroups of a single dataset. Let us imagine that we suspect that the sentence we have been investigating may be acceptable in some dialects of English but not others. We might split up our 60 subjects into two groups – speakers of American English versus British English – to compare the frequencies of a subject judging the sentence acceptable in the two groups. If we do not have exactly the same number of Americans as British people among our test subjects, we will have to compare percentages rather than counts between the categories, as is shown in Table 1.

Table 1 Some basic acceptability judgement results

Dialect	*American English*	*British English*	*Totals*
'sentence is acceptable'	22 (63%)	8 (32%)	30 (50%)
'sentence is not acceptable'	13 (37%)	17 (68%)	30 (50%)
Totals	35	25	60

We can see from the percentages what is not obvious from the raw count, that the frequency with which American speakers judge the sentence acceptable (63%) is very similar to the frequency with which British speakers judge it to be unacceptable (68%).

Type-Token Ratio

The type-token ratio is one of the basic measures used in looking at texts with statistical, corpus-based methods. A *token* is any single instance of a word in a text; comparing the number of tokens in the text to the number of types of tokens – where each *type* is a particular, unique word-form – can tell us how large a range of vocabulary is used in the text. For example, the sentence 'The cat sat on the mat' contains six tokens (*the, cat, sat, on, the,* and *mat*) but only five types (*the, cat, sat, on,* and *mat*). So its type-token ratio is $5 \div 6 = 0.83$ types per token.

As a text gets longer, the number of types that have already been encountered increases, and the likelihood of any given token representing a new type falls. For this reason, type-token ratio as a statistic is very sensitive to the length of the text. All other things being equal, a shorter text will have more types per token than a longer text. For instance, we saw above that the ratio for a single sample sentence was 0.83, but for 10 000 words of text it would be much, much lower.

For this reason, when comparing the type-token ratios of different texts, it is a good idea to make sure we are comparing equally-sized samples of the text.

Measuring a Central Tendency

In the simple example we discussed above, each subject was presented with a single sentence and asked to say whether it was acceptable or not. However, in reality, this test might be rather unreliable. We have no way of knowing whether this is a consistent usage

on the part of the subjects, or if it is just a guess. A slightly more sophisticated way to go about it would be to present each subject with a *number* of sentences incorporating the structure we are interested in and elicit a grammaticality judgment for each one.

Combining groups of subjects (for instance, American English speakers versus British English speakers) is more difficult in this case. We cannot simply say that *X* percent of American speakers and *Y* percent of British speakers thought the structure was acceptable, because we don't have yes/no judgments; we have a number (call it *A*) for each subject, which indicates how frequently that subject judged the structure acceptable.

One way to compare groups in this case is to summarize the *A* of a set of subjects to a single value which indicates where the average position – the central tendency – of the group is.

One way of calculating the central tendency in a group is by using the *mean* together with the *standard deviation*. The mean, also known as the average, is the sum of all of the values in a dataset or a subgroup of a dataset, divided by the number of values in that dataset or subgroup. So if we have three speakers of American English who, presented with 50 sentences, have (respectively) judged 37, 46, and 32 of them to be acceptable, then the mean number of sentences judged to be acceptable by this group of subjects is $(37 + 46 + 32) \div 3 = 38.3$.

The standard deviation is a statistic for measuring how spread out around the mean the values in a dataset are. Compare, for instance, the group of American speakers we just discussed with a second group, who judged (respectively) 42, 36, and 37 sentences to be acceptable. The mean value is the same (38.3) but clearly, the second group of subjects seem to have values that are closer to the mean than the first. The standard deviation reflects this.

The standard deviation is calculated as follows:

1. Calculate the deviation of each value in the set (this is equal to the mean of the dataset minus the value).
2. Square each deviation.
3. Find the mean of the squared deviations (add together all the squared deviations, and divide by the number of values in the set minus 1).
4. Find the square root of this mean – this is the standard deviation.

There are a number of variations on the standard deviation procedure used with more complicated datasets. However, the principle remains the same. In practice this, and the other complex calculations described in this article, are almost always done by computer, using programs such as the Statistical Package for the Social Sciences (SPSS) software. SPSS allows the automated calculation of a wide range of statistical procedures, including those covered here. Hence, we will not concern ourselves here with how to perform such calculations manually.

Table 2 shows an example of the mean and standard deviation being used with data from a hypothetical experiment of the type outlined above.

We see from this example that the mean number of sentences containing the structure we are interested in that were judged acceptable is much lower for British subjects than American subjects, but the distribution around the mean, as indicated by the standard deviation, is not much different between the two groups, i.e., while individuals varied in their responses greatly, the difference was less marked for the groups when considered as wholes.

For some purposes the mean and standard deviation are most useful for measuring the central tendency of a dataset; for others, the *median* and *interquartile range* are more useful.

The median is the middle value when all the values of a set are arranged in ascending order (or, if there are an even number of values, the mean of the two middle values). For instance, if we arrange the values from the speakers of American English above in order, we get:

0, 0, 8, 12, 17, 19, 20, 23, 24, 29, 29, 29, 30, 31, 32, 32, 33, **34**, 35, 35, 35, 37, 38, 39, 40, 43, 45, 47, 48, 50, 50, 50, 50, 50, 50

The median (highlighted) is the 18th value on the series – there are 35 speakers, so the 18th speaker is

Table 2 More complex acceptability judgement results

Dialect	*American English*	*British English*	*All*
Number of subjects	35	25	60
Number of sentences each subject judged acceptable (raw counts out of 50)	37, 48, 23, 50, 35, 50, 50, 20, 0, 50, 43, 38, 29, 31, 47, 0, 30, 24, 34, 45, 12, 8, 32, 50, 35, 32, 40, 39, 29, 19, 33, 35, 17, 29, 50.	0, 0, 50, 0, 28, 18, 38, 20, 25, 33, 0, 50, 23, 34, 48, 31, 22, 0, 19, 22, 7, 32, 25, 16, 27.	(see other columns)
Mean for group	32.7	22.7	28.5
Standard deviation for group	14.0	15.4	15.3

in the middle. Similarly, the median for the British English speakers is 23, and for the whole dataset it is 30.5. This is important, because the mean is not necessarily always the best indicator of central tendency in a dataset. Sometimes the median is a more useful measure.

The interquartile range is a way of measuring how spread out around the median the data is. In the same way that the median is found by looking at the value halfway along the ordered list of values, we can look at the data to see what value occurs a quarter of the way along, and three-quarters of the way along. These values are called the lower quartile and upper quartile, respectively, and the difference between them is called the interquartile range.

If we look at the values for all the speakers:

0, 0, 0, 0, 0, 0, 0, 7, 8, 12, 16, 17, 18, 19, **19**, **20**, 20, 22, 22, 23, 23, 24, 25, 25, 27, 28, 29, 29, 29, **30**, **31**, 31, 32, 32, 32, 33, 33, 34, 34, 35, 35, 35, 37, 38, **38**, **39**, 40, 43, 45, 47, 48, 48, 50, 50, 50, 50, 50, 50, 50, 50

There are 60 values altogether, so the median is the mean of the 30th and 31st values (30.5), the lower quartile is the mean of the 15th and 16th values (19.5), and the upper quartile is the mean of the 45th and 46th values (38.5). So the interquartile range is $38.5 - 19.5 = 19$. Again, there are occasions when the interquartile range may characterize a dataset better than either the mean, standard deviation or the median.

Grouped Data

Sometimes we do not know the exact values for each data point. For example, we might not know exactly how many sentences the subjects judged to be grammatically acceptable; we might instead have them classified into groups (Table 3).

In this case, calculating mean, median, standard deviation, and interquartile range is less straightforward than if we know all of the values. However, it is still possible to calculate these measures and to perform other statistical operations on grouped data. Procedures for getting these measures from such data are time consuming and complex, however, and would almost always be undertaken using a computer.

Table 3 Acceptability judgement results as grouped data

Number of sentences judged acceptable	*Number of subjects*
0 to 10	9
11 to 20	8
21 to 30	13
31 to 40	17
41 to 50	13
Total	60

Significance Tests

Most things that we want to measure are subject to a certain amount of 'random' fluctuation. In our example of the acceptability judgments made by American and British speakers of English, our measures of central tendency show that as a group the Americans find the structure more acceptable than the British.

However, some *individual* speakers in both groups have judged all of the sentences to be acceptable (score of 50) or judged all of the sentences to be unacceptable. So although it looks as if national dialect is one factor determining the acceptability of the structure we are looking at, other factors which we haven't yet identified are also playing a part. This could be anything from sex to age to educational background to personal preference.

Given that other factors are affecting our data, making it behave in a basically 'random' way, we have a problem. It may just be a coincidence – a product of the random variations in the values – that the average value for the Americans is higher than the average value for the British. The mean and median seem to show a difference between the two groups of subjects, but is it a real difference or just random chance?

We can use *significance tests*, such as the chi-square test, log-likelihood test or t-test, to assess how likely it is that a particular result is a coincidence, due simply to chance. By convention it is accepted that if there is a 95% chance that our result is not a coincidence, then we can say that the result is *significant*. Sometimes, we will want to be more certain than this that our results are not due to chance. In this case, we might want to ascertain whether our results, for example, are significant at the 99% level, that is, if there is less than a 1% chance that the results are due to error. A score of 95%, while it sounds impressive, means that we have a 1 in 20 chance of claiming significance falsely. By choosing a level of 99% we can be more confident in that result, as we will have only a 1 in 100 chance that we have claimed significance in error. A result that is not significant cannot be relied on, although it may be useful as an indication of where to start doing further research (maybe with a bigger sample of data).

The choice of an appropriate significance test (for example, chi-square or t-test) depends very much on what type of data we have. An example of the chi-square test is given in Case Study Two below.

Sampling

It is very rare that we can work on the full set of all of the data related to a language. Living languages are

typically not finite. So in corpus linguistics, for example, a corpus is only ever a sample of all the language that is produced. Similarly, in experiments involving acceptability judgments or elicitation tests, we can't usually ask every speaker of the language to be a test subject; we must make do with a sample of speakers.

Sampling is an important issue in statistics. Since we want to extrapolate from our sample to the whole population – from our test subjects to the whole population of speakers, or from our corpus to all the texts produced in the language – it is crucial that we get a sample that represents the population as well as possible.

One way to get a representative sample is to sample randomly, so every speaker or text has an equal chance of ending up in the dataset – so ideally, for instance, we would give every English speaker a number, and then use a random number generator on a computer to pick the speakers who were going to respond to our elicitation test. This level of randomness is practically impossible with people, but may be more practicable when choosing texts (e.g., taking a sample of sentences from a corpus, or a sample of texts from an electronic database, or a sample of days from a year's worth of a newspaper).

Another way to get a representative sample, if you wish to look at general language use, is to design your dataset in advance according to criteria that make the data as diverse as you can manage. You might decide, for instance, that you want 10 speakers (five male, five female) from each of a set of age groups you drew up beforehand. Or you might determine in advance that your corpus will be made up of 10% news reportage, 10% prose fiction, 10% academic texts, and so on.

In practice, however, when sampling either speakers or texts, it is often necessary simply to take what is available – since friendly people willing to give you the time to do a questionnaire, or the permission to use their text in a corpus, are sometimes in short supply.

An example of poor sampling would be to do a survey of opinions on nonstandard dialects by putting up a notice asking for people to write down their ideas and send them to you. This is not a representative sample because it is self-selected: only people with strong opinions are likely to get in touch. You might get some interesting responses, but they won't represent the views of the population as a whole! Similarly, you can bias the results of an acceptability judgment survey or elicitation test if your subjects are linguistics students or academics – the responses of people who spend their lives reflecting on language may well not represent the reactions of the typical speaker of the language.

Another example of poor sampling would be to walk up to a random shelf in the library and grab six books to use as your corpus. Books shelved closely together are likely to be similar in style or subject matter or both, so features particular to that type of book will predominate in your corpus.

More Complex Statistics

The statistics and estimates of probability used by some applications in computational linguistics are much more advanced and complicated statistics than those discussed so far. While there is insufficient space to cover such approaches here, it is useful to note that of particular importance to computational linguistics are probabilistic or stochastic models, which are based on manipulating statistics relating to the frequency of different phenomena in language. These models are used to help computers to simulate language production and comprehension tasks that humans perform using only their language faculty. Given the importance of such models, they are outlined, in brief, in this section.

An example of this is part-of-speech tagging, the computer process which analyses words in running text into their part-of-speech categories. One of several approaches to part-of-speech tagging uses a statistical model called a *hidden Markov model* to estimate the most likely part-of-speech category of a word, based on the words and categories around it. The Markov model is a mathematical formula which allows us to combine frequency statistics on different sequences of parts-of-speech to produce a very good prediction of what the unknown part-of-speech is.

Probabilistic models can perform very well on the linguistic tasks we set them, but never perfectly (since they are based on statistics, and therefore may not deal well with phenomena or patterns that are statistically uncommon but do occur from time to time).

Case Studies

There follow two entirely fictional case studies of statistics in use in linguistics. Although these examples are made up and simplified to an extent, many linguists use procedures similar to the ones demonstrated here every day.

Case Study One: Averages in Action

Professor Veebey is discovering corpus linguistics. Using a concordancer to search for all pronoun forms in the SNIFL (**S**elected **N**ovels **I**n **F**amous **L**iterature) and ATCHOO (**A**ncient **T**ext **C**orpus of **H**istorical **O**ratory and **O**des) corpora, he has come up with a very exciting result: the average number of pronouns

Table 4 Pronouns in the SNIFL data

	Text1	*Text2*	*Text3*	*Text4*
No. of pronouns	1024	1541	9943	1358

Mean = 3466.5 pronouns.

Table 5 Pronouns in the ATCHOO data

	File A	*File B*	*File C*	*File D*	*File E*
No. of pronouns	998	1819	854	1225	1362

Mean = 1251.6 pronouns.

in a SNIFL text (Table 4) is much higher than the average number of pronouns in a text from ATCHOO (Table 5)!

SNIFL data mean = 3466.5 pronouns.

ATCHOO data mean = 1251.6 pronouns.

Professor Veebey strongly suspects that this is due to a difference in genre – since SNIFL is made up of prose fiction and ATCHOO is made up of speeches and poetry. But his colleague Professor Seigh disagrees. She points out that he has used the mean, which may not be the best way to measure the central tendency of the data and, before leaving for her lunch, suggests he has a look at the median as well. Professor Veebey goes away and calculates the medians:

SNIFL pronoun counts in order: 1024, 1358, 1541, 9943. Median = 1449.5 pronouns.

ATCHOO pronoun counts in order: 854, 998, 1225, 1362, 1819. Median = 1225 pronouns.

So there is a difference in the median values, but nowhere near as large a difference as there is between the means. This is because the mean for the SNIFL corpus was distorted by the very large pronoun count in Text3. Professor Veebey is a little disheartened by this, but still thinks he might have something interesting. He is sadly disillusioned when Professor Jarver, who's not nearly in such a hurry to get to lunch, looks over his data.

The very first thing she points out is that he has failed to take into account the length of the text; knowing how many words are pronouns is not any use at all unless you know how many words there are altogether. A better way to look at the data would be to compute pronoun frequency in terms of pronouns per thousand words.

Oveall rate of pronouns per thousand words in SNIFL corpus = 114 (Table 6).

Table 6 SNIFL data, expressed 'per 1000 words'

	Text1	*Text2*	*Text3*	*Text4*	*Corpus*
No. of pronouns	1024	1541	9943	1358	13866
Words in text	9330	12461	87459	12561	121811
Pronouns per thousand words	110	124	114	108	114

Overall rate of pronouns per thousand words in ATCHOO corpus = 111 (Table 7).

Professor Jarver notes that the pronoun rates for the corpora as a whole are virtually the same (114 PTW and 111 PTW). Professor Jarver realizes that Professor Veebey's idea might not be so bad, if applied to the right data. So she digs out COFF (**C**orpus **O**f **F**ringe **F**lyers, which was collected by Professor Cowball while on holiday at the Edinburgh festival in 1998) and does a pronoun count for each file in the corpus (each file contains a handful of original texts). Her results are shown in Table 8.

Professor Jarver does not bother working out individual pronouns-per-thousand-words-rates for the separate files (or the separate texts within the files), because they are in general rather small and not terribly interesting. What she's really keen to know is the overall pronoun rate. It turns out that the COFF corpus contains 62 pronouns PTW. This is a *lot* less than in the other two corpora. So here there really might be a genuine genre difference between the general literary style seen in ATCHOO and SNIFL and the style of the promotional flyers collected in COFF. This might be a feature of the short length of COFF texts, or it might turn out to be the result of some other style factor. In any case, Professors Jarver, Seigh, and Veebey will need to do a lot more research – and a lot more statistics – to track down the answer.

Case Study Two: The Swigbal Morpheme Problem

In the 1930s, Professor Moresgood published the standard Swigbal grammar. (Swigbal is a fictitious language.) He observed that the two major dialects of Swigbal differed with respect to the form of the past-tense morpheme on intransitive verbs; North Swigbal formed the past tense with *kal* whereas South Swigbal formed it with *tal*. He also reported occasional use of an archaic form *lal* in both dialects.

Some decades later, Professor Betternot revisited the issue of Swigbal grammar. In her seminal paper, Betternot (1969), she used grammaticality judgments from a speaker of North Swigbal and a speaker of South Swigbal to demonstrate that *kal*, *tal*, and *lal*

Table 7 ATCHOO data, expressed 'per 1000 words'

	File A	*File B*	*File C*	*File D*	*File E*	*Corpus*
No. of pronouns	998	1819	854	1225	1362	6258
Words in text	9003	17521	7387	9997	12714	56622
Pronouns per thousand words	111	104	117	123	112	111

Table 8 Pronouns in the COFF data

COFF file name	*Number of pronouns*	*Number of words*
gstv	21	492
xkam	99	864
yjvb	111	2641
wrnt	72	656
pllq	0	787
qvfr	69	1003
tygr	32	322
qwps	130	1170
trps	101	749
kysh	23	2000
zcku	75	1901
oozb	74	323
mlvk	56	997
Whole corpus	863	13905

were all perfectly acceptable past-tense morphemes in both dialects. The paper was accepted as definitive at the time, in spite of being based upon nothing more than the judgment of one native speaker per dialect.

However, recent work carried out by Professor Wellmaybe seems to show that Moresgood may have been on the right track after all. Although both *kal* and *tal*, as well as *lal*, do occur in both dialects, there seems to be some evidence that *kal* is most frequent in North Swigbal, and *tal* in South Swigbal.

Wellmaybe's sample of Swigbal discourse contains 1118 intransitive past-tense verbs. Breaking them down into categories provides the frequency counts in Table 9.

The question we must ask is whether the difference we see between North Swigbal and South Swigbal in Wellmaybe's data is significant.

For this kind of data, we can use the chi-square test. (We'll see why it's called this later.) In statistical terms, what we want to do is test whether the use of *kal* and *tal* as a variable is independent of the variable of dialect or not.

If the two variables are independent, then Betternot was correct – there is no evidence of a difference between the dialects in this matter. If they are not

Table 9 Swigbal tense data

	Observed instances of the past tense with . . .			*Total*
	kal	*tal*	*lal*	
North Swigbal	250	142	31	423
South Swigbal	241	443	11	695
Total (whole dataset)	491	585	42	1118

independent, then there *is* a difference between the dialects with regard to the past tense.

We start by assuming that the two variables are independent. We then ask, what frequencies would we expect to see in a table like Table 9 if the two variables are independent? We can work out these expected frequencies if we look just at the combined frequencies of *kal* and *tal* for both dialects, and at the total number of instances of the past tense that we have for each dialect.

For both dialects taken together, 43.9% (491 out of 1118) of past tense instances use *kal*, 52.3% (585 out of 1118) use *tal*, and 3.8% (42 out of 1118) use *lal*. If the variables are independent, we would expect these percentages to be reflected in the figures for each individual dialect – if there is not a dialect difference, then splitting up our sample of past-tense utterances shouldn't drastically affect the proportions of each morpheme that occur. So our expected frequencies work out as shown in Table 10 (with decimal places rounded to the nearest whole number of instances).

Remember that a percentage is just a way of expressing one value divided by another as an 'out of one hundred' figure. 186 out of 423 and 305 out of 695 are both equivalent to 491 out of 1118 (43.9%).

We can generalize and rearrange this and say that the expected frequency for any cell is equal to the total for the row the cell is in, multiplied by the total for the column the cell is in, divided by the overall total for the table (the sample size):

Cell's expected frequency =
(row total × column total) ÷ sample size

Clearly, these expected frequencies are different from the frequencies we've actually got in our data. But how different are they, and is the difference significant? We work this out by calculating a statistic called chi-square.

We start by subtracting the expected frequencies from the observed frequencies in each cell of Table 11. The row and column totals are not needed for this calculation, so they have been left off the table.

In this particular case, the differences we get in the North Swigbal row and the South Swigbal row are exactly the same, but with opposite signs – this

is because there are only two rows, and the row totals are fixed, so any increase in one row leads to a same-size decrease in the other row.

We can now calculate an overall statistic for the amount of difference between the observed frequencies and the expected frequencies. We start by taking the square of the value in each cell, as shown in Table 12 (this is done to make all the values positive).

Not all differences between observed and expected frequencies are equally important. For example, the difference between an observed frequency of 4 and an expected frequency of 6 is **2**. There is the same difference between an observed frequency of 125 and 127 – but obviously the difference of 2 is a much bigger deal if the expected frequency is only 6! To account for this, we divide each squared difference by the corresponding expected frequency (Table 13).

If you've been keeping track, you'll know that the values we have now are:

(Observed frequency – Expected frequency) ÷ Expected frequency

The last step is to add up all the values for the table, to get a single statistic that measures how much difference there is between observed and expected frequencies across the table as a whole. This statistic is called chi-square.

Chi-square for the Swigbal data =
$22.02 + 33.55 + 14.06 + 13.43 + 17.14 + 8.65 = \mathbf{108.85}$

The way chi-square is calculated means that it is a standard statistic across all datasets. Statisticians have therefore been able to use the probability distribution of chi-square to create standard tables. We use these tables to work out how large chi-square has to be for there to be a significant difference between the frequencies we observe and the frequencies we'd expect if the two variables (in this case, dialect and past-tense morpheme) were not related.

To know which bit of the chi-square table to look at, we have to measure the size of our table – after all, the importance of a difference of a particular size may mean more or less, depending on how many options there are in a table. We measure the table's size in 'degrees of freedom' (d.f.), which we calculate by multiplying the number of rows minus one by the number of columns minus one – not counting rows and columns that only contain labels or totals. So for this set of data,

$$\text{d.f.} = (3-1) \times (2-1) = 2$$

We want to be at least 95% certain that our results are not due to chance alone. The mathematical way of expressing this is $\alpha = 0.05$ (a 5% chance that our results are due to chance). If we look on the chi-square table for the value for d.f. = 2 and $\alpha = 0.05$, we find the value of 7.81. This means the chi-square for our dataset must be greater than 7.81 for our results to be significant at this level.

The chi-square for the Swigbal data is 108.85, which is higher than 7.81, so we can say with at least 95% confidence that the difference between the observed and expected frequencies is not just due to chance. Since we based our expected frequencies on the assumption that the dialect of Swigbal being spoken did *not* influence the form of the past tense morpheme, we can therefore be at least 95% confident that this assumption was not correct, and that the dialect *does* affect the form of the past tense morpheme.

So we can say that Professor Wellmaybe's data does show significantly that there is a difference between the North Swigbal and South Swigbal dialects.

Chi square does not always demonstrate that a difference is significant of course, as is demonstrated by the case of Professor Appentwill's work on Ranjumi. The Ranjumi language is closely related to

Table 10 Expected frequencies (Swigbal tense data)

	Expected instances of the past tense with . . .			*Total*
	kal	*tal*	*lal*	
North Swigbal	186	221	16	423
South Swigbal	305	364	26	695
Total (both dialects)	491 (43.9% of 1118)	585 (52.3% of 1118)	42 (3.8% of 1118)	1118

Table 11 Chi-square calculation, step 1

	Observed minus *Expected frequencies*		
	kal	*tal*	*lal*
North Swigbal	250 − 186 = 64	142 − 221 = −79	31 − 16 = 15
South Swigbal	241 − 305 = −64	443 − 364 = 79	11 − 26 = −15

Table 12 Chi-square calculation, step 2

$(64)^2 = 4096$	$(-79)^2 = 6241$	$(15)^2 = 225$
$(-64)^2 = 4096$	$(79)^2 = 6241$	$(-15)^2 = 225$

Table 13 Chi-square calculation, step 3

$4096 \div 186 = 22.02$	$6241 \div 186 = 33.55$	$225 \div 16 = 14.06$
$4096 \div 305 = 13.43$	$6241 \div 364 = 17.14$	$225 \div 26 = 8.65$

Table 14 Ranjumi tense data

	Observed and Expected instances of the past tense with...			*Total*
	kar	*tar*	*lar*	
West Ranjumi	O: 80 *E: 74*	O: 11 *E: 18*	O: 9 *E: 9*	101
East Ranjumi	O: 61 *E: 67*	O: 23 *E: 16*	O: 9 *E: 9*	92
Total (whole dataset)	141	34	18	193

Swigbal, and has three similar past-tense morphemes, *kar, tar,* and *lar.* Professor Appentwill has supplied some data that suggests that West Ranjumi and East Ranjumi behave similarly to North Swigbal and South Swigbal with regard to the variation in the past tense. Both dialects favor *kar* over *tar,* but the difference is greater in West Ranjumi than East Ranjumi.

This data is shown in Table 14, together with the expected frequencies calculated from the row, column and table totals.

Observed minus Expected values are calculated in Table 15.

The differences are squared in Table 16.

In Table 17, the results are divided by expected frequencies.

Table 15 Chi-square calculation, step 1

$80 - 74 = \mathbf{6}$	$61 - 67 = \mathbf{-6}$	$11 - 18 = \mathbf{-7}$	$23 - 16 = \mathbf{7}$	$9 - 9 = \mathbf{0}$	$9 - 9 = \mathbf{0}$

Table 16 Chi-square calculation, step 2

36	36	49	49	0	0

Table 17 Chi-square calculation, step 3

$36 \div 74 = 0.49$	$36 \div 67 = 0.54$	$49 \div 18 = 2.72$	$49 \div 16 = 3.06$	$0 \div 9 = 0$	$0 \div 9 = 0$

Finally, the values in Table 17 are added up to find the chi-square = **6.81**.

The critical value is the same as it was for the last dataset, since we are still dealing with 2 degrees of freedom and a 95% confidence that the difference is not due to chance ($\alpha = 0.05$); for the result to be significant, chi-square needs to be greater than 7.81 – but it isn't. Chi-square for this dataset is only 6.81, so there is a greater than 5% probability that these results are just due to chance. Therefore, the apparent effect of dialect on the form of the past tense is not statistically significant.

So while the Ranjumi data make it look as if *kar* is more common in West Ranjumi than East Ranjumi, the statistics tell us that this result just isn't significant – it's back to the drawing board for Professor Appentwill.

Steele, Joshua (1700–1791)

J Kelly, University of York, York, UK

© 2006 Elsevier Ltd. All rights reserved.

The Honorable Joshua Steele, businessman, phonetician, and humanitarian, was born in Ireland. He lived for a considerable time in London and in 1756 was elected a member of the Royal Society of Arts, later becoming its vice president. He produced but one book (*An essay towards establishing the melody and measure of speech*, 1775), which came out twice; on the second occasion in 1779, it was under the new title *Prosodia rationalis*.

In the second volume of his study of language, the Scottish writer James Burnett, Lord Monboddo, had expressed the view that "the music of our language [is] nothing better than the music of a drum"; (Burnett, 1773–1792); that is, that pitch variation

played no significant part in the working of the English sound-system. Steele wished to take issue with this; and his book was in the form of an exchange of writings between himself and Monboddo. Steele's contribution, by far the more extensive, provided us with the first sophisticated study of English intonation, and anticipated a number of ideas that were to be fully developed only much later on. For example, he linked the analysis of intonation with that of other constituents of speech, such as rhythm, the 'measure' of his title. He recognized five 'accidents of speech, namely 'accent,' 'quantity,' 'pause,' 'emphasis,' and 'force,' assigning a set of symbols to each of these. His treatment of rhythm saw it as relatively abstract and allowed for a basic pulse of the rhythmical system to coincide with pause, as with the 'silent stress' of later writers. He thereby introduced new possibilities for the analysis and typology of verse structure. Monboddo admitted to being "fully convinced that there is both a melody and rhythm . . . in English" (Steele, 1775).

Steele's essay also had practical objectives, in that he wanted to see the notation system that accompanied his analysis used to 'express and perpetuate' such things as the minutiae of speech as used in performance by distinguished actors of his day.

In midlife, Steele had spent time in Barbados, and in 1781 he traveled back there to run an estate of more than 1000 acres which had become his. He became a member of the council of the island and eventually chief justice. He founded at Bridgetown a society modeled on the London Royal Society of Arts, but it had as a more particular purpose the introduction of reform in the treatment of slaves on Barbados plantations. He himself introduced a system of payment to slaves in his employ and gave them parcels of land on his estate. The subsequent increased prosperity of his business demonstrated to his fellow plantation owners the efficacy of such humane policies. Steele died in Barbados.

Steinthal, Heymann (1823–1899)

K-Å Forsgren, Umeå University, Umeå, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Heymann Steinthal was a German linguist and philosopher of languages. He was born in 1823 in Gröbzig near Bernburg on the Saale and died in 1899 in Berlin. From 1843 Steinthal studied languages, philology, and philosophy in Berlin under teachers such as J. Grimm, F. Bopp, A. Trendelenburg, and H. K. W. Heyse. In 1847 he became a Ph.D. and habilitated in 1849. From 1852 he spent 4 years in Paris and London studying Chinese and African languages. He was appointed an associate ('außerordentlicher') professor in 1862. Steinthal also became close friends with Moritz Lazarus (1824–1903), through whom he was introduced to the psychology of J. F. Herbart. In spite of his high qualifications Steinthal never received a permanent position as a professor, probably due to his Jewish origin.

Steinthal's dissertation *De pronomine relativo* (1847) and habilitation thesis (*Die Sprachwissenschaft Wilhelm von Humboldts,* 1849) were the beginnings of a lifelong struggle with von Humboldt's work, in which also the philosophy of Hegel plays an important part. In 1850 *Die Classification der Sprachen* appeared, typology of languages being one of Steinthal's main interests. In his *Ursprung der Sprache* (1851) the origin of language is explained by means of Humboldt's famous principle underlying everyday speech: language is ***energeia*** ('activity'), not ***ergon*** ('the result of activity'). Steinthal's turn to Herbart's psychology led to a vehement attack on rationalist grammar (*Sprache, Logik und Psychologie,* 1855) as it was represented by K. F. Becker, also a follower of Humboldt. The purpose was to refute the idea that language and thinking are identical and to substitute logic as basic to grammar for the wider scope that psychology could provide. It is noteworthy that Becker's syntactic system remained untouched and was even used by Steinthal. Psychology, the idea of *Volksgeist* (roughly, 'national character'), *innere Form*, i.e., Humboldt's hypothesis that the language determines a people's view of the

played no significant part in the working of the English sound-system. Steele wished to take issue with this; and his book was in the form of an exchange of writings between himself and Monboddo. Steele's contribution, by far the more extensive, provided us with the first sophisticated study of English intonation, and anticipated a number of ideas that were to be fully developed only much later on. For example, he linked the analysis of intonation with that of other constituents of speech, such as rhythm, the 'measure' of his title. He recognized five 'accidents of speech, namely 'accent,' 'quantity,' 'pause,' 'emphasis,' and 'force,' assigning a set of symbols to each of these. His treatment of rhythm saw it as relatively abstract and allowed for a basic pulse of the rhythmical system to coincide with pause, as with the 'silent stress' of later writers. He thereby introduced new possibilities for the analysis and typology of verse structure. Monboddo admitted to being "fully convinced that there is both a melody and rhythm . . . in English" (Steele, 1775).

Steele's essay also had practical objectives, in that he wanted to see the notation system that accompanied his analysis used to 'express and perpetuate' such things as the minutiae of speech as used in performance by distinguished actors of his day.

In midlife, Steele had spent time in Barbados, and in 1781 he traveled back there to run an estate of more than 1000 acres which had become his. He became a member of the council of the island and eventually chief justice. Heymann Steinthal was a German linguist and philosopher of languages. He was born in 1823 in Gröbzig near Bernburg on the Saale and died in 1899 in Berlin. From 1843 Steinthal studied languages, philology, and philosophy in Berlin under teachers such as J. Grimm, F. Bopp, A. Trendelenburg, and H. K. W. Heyse. In 1847 he became a Ph.D. and habilitated in 1849. From 1852 he spent 4 years in Paris and London studying Chinese and African languages. He was appointed an associate ('außerordentlicher') professor in 1862. Steinthal also became close friends with Moritz Lazarus (1824–1903), through whom he was introduced to the psychology of J. F. Herbart. In spite of his high qualifications Steinthal never received a permanent position as a professor, probably due to his Jewish origin.

Steinthal's dissertation *De pronomine relativo* (1847) and habilitation thesis (*Die Sprachwissenschaft Wilhelm von Humboldts,* 1849) were the beginnings of a lifelong struggle with von Humboldt's work, in which also the philosophy of Hegel plays an important part. In 1850 *Die Classification der Sprachen* appeared, typology of languages being one of Steinthal's main interests. In his *Ursprung der Sprache* (1851) the origin of language is explained by means of Humboldt's famous principle underlying everyday speech: language is ***energeia*** ('activity'), not ***ergon*** ('the result of activity'). Steinthal's turn to Herbart's psychology led to a vehement attack on rationalist grammar (*Sprache, Logik und Psychologie,* 1855) as it was represented by K. F. Becker, also a follower of Humboldt. The purpose was to refute the idea that language and thinking are identical and to substitute logic as basic to grammar for the wider scope that psychology could provide. It is noteworthy that Becker's syntactic system remained untouched and was even used by Steinthal. Psychology, the idea of *Volksgeist* (roughly, 'national character'), *innere Form*, i.e., Humboldt's hypothesis that the language determines a people's view of the

world, (but Steinthal, however, interpreted it the other way around; cf. di Cesare, 1996), and Hegel's notion of superindividuality are manifested in the idea of '*Völkerpsychologie*,' developed in *Zeitschrift für die Völkerpsychologie und Sprachwissenschaft* (20 vols, 1860–1890, jointly edited with Lazarus). It was established as a sociologic discipline in the 20th century. Classification of languages, psychology, logic, grammar, *Völkerpsychologie*, and Humboldt's philosophy are further taken up in publications such as *Die Mande-Neger-Sprachen. Psychologisch und phonetisch betrachtet* (1867), *Geschichte der Sprachwissenschaft bei den Griechen und Römern mit besonderer Rücksicht auf die Logik* (1862), *Einleitung in die Psychologie und Sprachwissenschaft* (1871), and *Über Wilhelm von Humboldt* (1883), to mention a few of them apart from his works on religion, ethics, and Judaism.

As an intellectual Steinthal was a complicated character, of great influence (on H. Paul, W. Wundt, W. Dilthey, and others), sharp eyed, clear, consequent, inquiring, and controversial (A. Marty and W. D. Whitney were two of his opponents), often hypercritical and presumptuous. He certainly contributed to liberating grammar from logical speculation, even if his attempt to apply a psychological theory failed and was hardly less speculative. Like Humboldt he mainly adopted a synchronic perspective in his comparative studies, anticipating a new paradigm to come in respectful opposition to the mighty historic-comparative environment of his time. His typological and historiographical studies (*Geschichte der Sprachwissenschaft,* 1862) are still of interest and useful today.

Stemming

C D Paice, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Stemming is the process of removing affixes from a word in order to obtain its stem, and a stemmer is an algorithm that performs this process. The purpose of stemming is the conflation of morphologically and semantically related words. Thus, a stemmer might reduce the words *computed*, *computing*, and *computation* to the stem *comput*. Note that the stem does not have to be an actual word, although it often is.

Stemming is widely used in information retrieval (IR) systems to standardize the vocabulary for indexing and searching. Thus, if a document in a database contains the word *computing* and a searcher's query includes the term *computation*, the use of a stemmer ensures that these are recognized as matching terms. An additional benefit is that the size of the indexing vocabulary is reduced because a document need not be indexed by every variant that it contains.

In principle, a stemmer may remove both suffixes and prefixes. In English, the removal of prefixes is not generally considered helpful (consider the effect of removing the prefixes from *com-pute* and *dis-pute*). In some other languages, prefix removal is more desirable, and, in some, infixes also may need to be deleted. Arabic is a notable example; an Arabic word may consist of an alternation of affixes and stem fragments. Stemmers for such languages are quite complex, and here we focus mainly on straightforward suffix-stripping stemmers.

A typical stemmer does not necessarily just delete characters from a word – it may also need to modify the resulting form to obtain a satisfactory stem. Thus, the deletion of the endings *-ion* and *-ing* from *collision* and *colliding* gives *collis* and *collid* – so one at least of these should be further modified to achieve conflation.

The obvious way to perform stemming is to check the ending of each incoming word to see if any action is needed. The detailed rules may be either expressed in the form of actual program code (hardwired) or set out in one or more tables, with a driver program for comparing each input word against entries in the table. Constraints are generally applied to prevent absurdities such as the reduction of *rant*, *red*, *rent* and *ring* to the stem *r*. Linguistic stemmers do not rely on a prespecified set of endings but, instead, use a machine-readable dictionary to determine the base form of a word.

In 1968, Julie Beth Lovins published a description of a stemmer that uses a table of endings to convert an input word in one step to a raw stem, and then a table of recoding rules to make final adjustments, including the singling of final consonants. The popular Porter's (1980) stemmer removes or modifies endings in five main stages, first dealing with the inflective endings *-s*, *-ed*, and *-ing* and then tackling all the derivational endings. Because of the rather complex organization of the rules, implementations of Porter's stemmer are usually hardwired. The Paice/Husk stemmer (Paice, 1990) uses a single table of rules in which an ending, if found, is either deleted or replaced. The rules are applied iteratively, so that a long ending such as *-ationally* is removed in several stages; in contrast to Porter's method, the number and ordering of the stages are not prescribed.

Stemmers are now available for many natural languages, although this has often involved the development of a specialized algorithm tailored to the features of the language concerned. It may be possible to adapt an existing table-driven stemmer to a new language quite easily, but this still leaves the task of developing the actual rule set. There is now an interest in generating rule sets automatically using a large corpus of texts in the language concerned; hidden Markov models or other statistical approaches may be used.

In view of their widespread use in IR systems, it is natural to assess stemmers by measuring their effects on retrieval performance (RP). Early results reported for English stemmers showed a confused picture, with no evidence of a clear and reliable benefit. Subsequent work, by Krovetz (1993) and by Hull (1996), indicated that stemming is helpful in cases in which the query or the document is short, but otherwise it is not. However, in more highly inflected languages, the benefits of stemming are often much clearer. Note, also, that reduction in vocabulary size may be worthwhile even if RP is not improved at all.

A disadvantage of measuring stemming effectiveness in terms of RP is that it provides no direct information about the causes of poor performance. Hull's investigation included a detailed analysis that revealed some of the factors at work but did not provide clear solutions. Paice (1996) took a different approach to measuring stemmer performance. This entailed taking a text sample, counting the number of understemming errors (failures to conflate) and overstemming errors (wrong conflations), and relating these to the number of pairwise conflations that should have been achieved. This approach is hampered by its reliance on human judgments about which words ought to be conflated; this not only introduces an element of subjectivity into the process, but also makes it very time-intensive, due to the need for manual grouping of thousands of words.

Various attempts have been made to improve the accuracy of stemmers. Krovetz developed a linguistic stemmer (KSTEM) in which dictionary lookup is used to resolve various problems, for example, to decide whether to retain the *e* when an *-ed* ending is removed. In some cases, KSTEM gave slightly better RP results than Porter's stemmer, but overall the picture was unclear. Another factor that can be used to guide a stemming decision is the part of speech of the word concerned, as in Savoy's (1993) stemmer for French.

A typical English stemmer often forms large conflation groups containing words that are only slightly related, thus degrading performance. Xu and Croft (1998) investigated a technique in which the stem groups formed by an existing stemmer (Porter's or KSTEM) were split into smaller groups using term cooccurrence data from a text corpus. They obtained small, but in some cases significant, improvements relative to the baseline stemmers.

Techniques other than affix removal are available for conflating variant forms of words; for instance, Adamson and Boreham (1974) proposed breaking each word into a set of digrams (letter pairs), and computing the degree of similarity between the digram sets for pairs of words.

Stephanus, Henricus (1531–1598)

S Matthaios, University of Cyprus, Nicosia, Cyprus

© 2006 Elsevier Ltd. All rights reserved.

Henricus Stephanus was a scholar, philologist, and publisher, one of the most important representatives of humanism and the French renaissance of the 15th and 16th centuries, along with Guillame Budé (1468–1540) and Joseph Justus Scaliger (1540–1609). Henri É(s)tienne, the eldest son of Robert É(s)tienne, was born in Paris in 1531 and died in Lyon in 1598. From early on, he attended lectures on classical philology in the Collège Royal of Paris. Apart from Latin, which he knew almost at the level of mother tongue, Henri also learnt Greek, for which he showed a great love and impressive familiarity. The offspring of one of the most well-known publishing dynasties in France, Henri undertook the directorship of the family printing house after his father's death in 1559. His father Robert, who directed the business initially in Paris and then in Geneva, was also engaged as an author, printer, and editor; on the publishing activities of the É(s)tienne family see Pattison (1889) and Widmann (1970).

Henri developed an extraordinary philological activity, which was tightly linked with his publishing. He traveled all over Europe in search of manuscripts, which he later edited und published. He completed no less than 74 editions of works by Greek writers, including many first editions (*editiones principes*); on Henri's editions see Lehmann (1956–1960: I, 82). His name is connected with an edition of *Anacreontea* (1554), which is based on a manuscript that Henri himself discovered in Italy (or Louvain); with the first edition of the fragments of lyric poets (1560); with a collection of epigrams, *Anthologia Planudea* (1566); and last, but not least, with an edition of Plato (*Platonis opera quae extant omnia* [...] *excudebat Henricus Stephanus* [1578]), the pagination of which is still today the standard way of citation. Apart from his Greek editions, Henri also edited 58 Latin and 3 Jewish writers, and he wrote and published 30 books in French and Latin. From the last category of his works, it is worth mentioning the book *De criticis veteribus Graecis et Latinis* (1587), which constituted the first modern history of classical philology.

Well beyond the limits of classical philology, Henri É(s)tienne was well known for his 5-volume dictionary *θησαυρὸς τῆς 'ελληνικῆς γλώσσης* (*Thesaurus Graecae Linguae*), which was published in 1572. As the counterpart of his father Robert's dictionary, *Latinae Linguae Thesaurus* (1543), this one deserved to be considered Henri's most important scholarly achievement. Its compilation was based on excerpts from no less than 140 works by then known Greek writers. Henri attempted to provide a hierarchy of the meanings associated with words, and for each meaning he cited evidence coming from the excerpts. Henri's *Thesaurus* was republished twice during the course of the 19th century, first in London and then in Paris, each edition being enlarged and more complete than the previous one. This piece of work constituted the cornerstone and the foundation of the scientific lexicography of Greek, as well as of the dictionaries of the modern times (cf. Cohn, 1913: 709, 712–713).

Stephanus, Robertus (ca. 1503–1559)

B Colombat, École Normale Supérieure Lettres et Sciences Humaines, Lyons, France

© 2006 Elsevier Ltd. All rights reserved.

Robertus Stephanus (Robert Estienne I), who was born in Paris c. 1503 (or 1498, according to Brandon, 1904: 6) and died in Geneva on September 7, 1559, is known as a printer, a lexicographer, and a grammarian. He was a member of a family of printers (his father, Henri I; his brother, Charles; his father-in-law, Josse Bade Ascensius; and his son, Henri II; *see* **Stephanus, Henricus (1531–1598)**). He studied Greek and Latin and was appointed the king's printer by François I for Hebrew and Latin in 1539 and for Greek c. 1540. In 1547, he was persecuted by the Sorbonne because of his biblical editions: the Bible in Latin (1528), the New Testament in Hebrew (1539), and the New Testament in Greek (1546, and many other editions), and went into exile in Calvinist Geneva (November 1550), where he continued printing until his death.

For biblical editions, Robertus Stephanus used strict philological rules. He also published many works of contemporary grammarians (Melanchthon, Linacre, Erasmus, Sylvius, Cordier, Bovelles, Despauterius, Valla, Budé, Clenardus, and Pagninius).

He gave up editing Calepino's dictionary (although he later published an edition in Geneva in 1553–1554), choosing instead to publish an original lexicographical work in 1531: *Dictionarium, seu Latinae linguae thesaurus, cum Gallica fere interpretatione* (augmented in 1536), a medium-sized dictionary of the Latin language, with a few explanations in French. From this work, he extracted the following works intended for different intellectual requirements and commercial targets:

1. the monumental *Thesaurus linguae Latinae* (1543). Essentially monolingual, with very long lists of quotations, despite a few errors due to Robertus Stephanus's haste in compilation, it remained the reference Latin dictionary for two centuries;
2. two intermediate-level dictionaries: the *Dictionarium Latino-Gallicum (DLG)* (1538) and the *Dictionnaire françois-latin (DFL)* (1539), of which the 1549 edition is considered the foundation of the French lexicography;
3. elementary dictionaries: a *Dictionariolum puerorum* (derived from the *DLG*) and *Les mots françois selon l'ordre des lettres* (derived from the *DFL*).

Robertus Stephanus's lexicographical works are closely linked to the Biblical editions, and his most important goal was always the knowledge of the Latin – not the French – language, for which he promoted a classical and purified use. But Robertus Stephanus also wrote many pedagogical treatises for translation between Latin and French, such as *La manière de tourner toutes espèces de noms latins en notre langue françoyse*, *Les déclinaisons des noms et des verbes*, *La manière de tourner les noms, pronoms, verbes*, and *Traicté de la grammaire françoise* (1557), which, although largely inspired by the grammars of Sylvius (1531) and Meigret (1550), has the pedagogical advantage of offering a very clear and pleasant presentation.

Stereotype Semantics

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

The term 'stereotype' was borrowed from French *edition stéréotype* in the late 18th century to denote printing from a solid metal plate of typeface cast from a mould. In the 19th and 20th centuries, stereotype was metaphorically extended to members of social groups (genders, races, social classes, professions, trades, criminals and other misfits, etc.) deemed to be typified by a set of (often pejorative) characteristics, for example, "as early as two years of age, most children select toys and activities that fit the sex-role stereotypes of their culture" and "Feminists in western developed countries have agitated against mass-media presentations of women that seemed biased, stereotypical, or discriminatory" (*Encyclopedia Britannica,* 2001). Many social groups are identified with a stereotypical jargon or sublanguage.

Against this background, Putnam (1975) proposed stereotype semantics, which I define as follows:

> The meaning of a language expression *e* (typically a lexeme) is not a well-defined set of properties necessarily found in every denotatum for the expression, it is rather a minimum set of stereotypical facts about the typical denotatum.

(Denotation is the relation between language expression *e* and things or events in the model of the world and time spoken of; a denotatum is potentially a referent.) Like prototype semantics, stereotype semantics is an alternative to theories of meaning that postulate a checklist of properties to be satisfied for the correct use of the expression *e* (Fillmore, 1975: 123). For example, the denotatum of *bird* is expected to be bipedal, have feathers, and be capable of flight. But:

- There are several species of flightless birds (e.g., emus, ostriches, and penguins).
- A downy chick and a plucked chicken are featherless but nonetheless birds.
- A one-legged bird and a mutant three-legged bird are also birds.

So the notion of a checklist of essential properties for the denotatum of *e* is problematical.

Putnam's notion of a stereotype incorporates connotation (*see* **Connotation**). Connotations of *e* arise from encyclopedic knowledge about the denotation of *e* and also from experiences, beliefs, and prejudices about the context in which *e* is typically used. Connotations vary between contexts and speech communities independently of sense and denotation: A male chauvinist and a radical feminist will possibly have quite different stereotypes for *man* and *woman* and yet have no difficulty picking the denotatum of one from the other. The relationship between lexical and encyclopedic knowledge is controversial (*see* **Dictionaries and Encyclopedias: Relationship**). Many scholars believe that all information about listemes should be included in the lexicon; others favor a division of labor between the lexicon as a bin for storing listemes and an encyclopedia as a structured database containing exhaustive information on all branches of knowledge. Allan (2001) argued that the lexicon is that part of the encyclopedia, which stores information about the formal, morphosyntactic, and semantic specifications of listemes, and that these are networked with other modules of information in the encyclopedia. Postulating close links between lexical and encyclopedic information nicely accommodates Putnam's notion of a stereotype. For example, the stereotypical bird flies, even though emus, ostriches, and penguins do not; flightlessness is a fact that should appear in the lexicon entries for *emu, ostrich,* and *penguin,* for example, to condition an appropriate interpretation of *the ostrich flew by.* The stereotypical politician is economical with the truth when his or her power or credibility is threatened, but this connotation is part of the encyclopedic data that have no place in the lexicon entry for *politician.* Putnam expressly allows for experts to have considerably more knowledge at their command than their fellows – which raises the interesting question: Do the words *elm* and *beech* have the same stereotype and meaning for a botanist that they do for an inner-city dweller who cannot distinguish an elm from a beech? Presumably not. However, if the botanist were to point out and name an elm, the inner-city dweller would know that that tree is not a beech, even if she or he could still not recognize another elm thereafter.

Similar to the stereotype is the notion of a Gestalt (single mental image). Three examples of the use of Gestalten in perception are:

- Knowing the true configuration of a chair even though we can only ever see parts of it from a single viewpoint.
- Recognizing melody without being conscious of the individual notes from which it is constructed.
- Having a Gestalt of a particular word enables us to 'feel' that it is spelled correctly or incorrectly on a given occasion.

A Gestalt is more like the stereotype in stereotype semantics than it is like the prototype of prototype semantics.

Prototype semantics (*see* **Prototype Semantics**) selects a particular denotatum or a particular sense as the most typical exemplar for a lexeme. Categories such as Rugs and Carpets (corresponding to the lexemes *rug* and *carpet*) or Cups and Mugs (corresponding to *cup* and *mug*) seem to merge gradually one into another, although prototypical exemplars of each category are clearly different (Labov, 1978; Allan, 2001). Lakoff (1972) proposed using fuzzy sets to index the exemplariness of a category member. The prototype is given the value 1.0; the worst example has a value close to 0.0. Although values of fuzzy set membership can be calculated from experiments such as the one described in Battig and Montague (1969), the achieved value is only valid for the tested population at the time of the experiment, not for all speakers of the language and not even for the same subjects on a different occasion. For instance, Rosch (1973) found that the common cold is a very poor exemplar of Disease – which conflicts with the Battig and Montague finding; the disparity is either a function of (1) the different experimental methods (Battig and Montague's subjects generated their own lists, but Rosch gave hers a choice among only six diseases, of which a cold is the mildest) or (2) the proportion of experimental subjects suffering from colds at the time of the experiment, making the cold salient. Rosch claimed that a robin is a good exemplar of the category Bird (lexeme *bird*) for North Americans. It would not be so good for Australians, for whom the emu ranks much higher because the emu is a national icon (similarly with the flightless kiwi for New Zealanders). Battig and Montague's figures demonstrate that a tomato is more of a vegetable than a fruit (0.68 vs. 0.14), but they do not reveal anything new about the meaning of the lexemes *tomato, vegetable,* and *fruit*. A tomato is both a fruit and a vegetable, but mostly it is used like a vegetable. Its characteristics are included in the internalized (cognitive) model of the tomato and contribute to the semantic frame of *tomato*. Prototype theory has no means of representing such facts. Even the poorest examples of a category remain within the category; the fact that an onion is a poor exemplar of a vegetable for a tested population does not change the subjects' perception that it is a vegetable. The prototype in no way defines the category – no one believes that a vegetable is a carrot! Furthermore, categories are independent of related categories with respect to prototypicality. For instance, a guppy is a good exemplar of the category Pet Fish, but it is not a good exemplar of either of the categories Pet or Fish. All in all, prototype semantics has failed to deliver startling insights into semantics (Osherson and Smith, 1981; Pulman, 1983; Kamp and Partee, 1995; Fodor and Lepore, 1996; and, for a contrary view, Lakoff, 1987; *see* **Prototype Semantics**).

Using the following story, Coleman and Kay (1981) discussed the difference between prototypical and typical characteristics (the latter is referred to in the Putnam's definition):

> A young man is involved in an automobile accident in which his father is killed. Seriously injured, the youth is rushed to hospital and a surgeon is called. Seeing the patient, the surgeon exclaims 'Oh my God! I can't possibly operate on my own son!'

The conundrum is founded on the fact that the (stereo) typical surgeon is male, and the surgeon in the story has to be the boy's mother. Coleman and Kay (1981: 36) wrote, "femaleness is by no means a property of TYPICAL surgeons" [*sic*]. Coleman and Kay (1981: 37) equated prototypical properties with denotation and typical properties with a connotation of *surgeon*: "prototypical properties play a role in the meanings of words, while merely typical properties do not". A "female surgeon is no less a surgeon for being female, though female surgeons may be as rare as hens' teeth" (Coleman and Kay, 1981: 36). There is no need to constrain the terms 'prototypical' and 'typical' in this way. The lexicon entry for *surgeon* will identify the lexeme's semantics and be networked with encyclopedic data that (perhaps) contain information on gender bias.

Cruse (1990) offered a different objection to the term 'typical.' He said that prototypicality seems to imply 'well-formedness.' A prototypical bird has two legs, two wings, one beak, and so on; injured birds and mutants do not fit the prototype nor do they fit the stereotype. He then raises the following point (Cruse, 1990: 385):

> Anyone who is fond of collecting edible wild fungi, for instance, will know that well-formed specimens are in the minority: most are damaged, decayed or maggot-ridden, and the finding of an unblemished specimen is an occasion for rejoicing. One might hazard a guess that the typical mushroom is not well-formed.

Cruse's term 'typical' is close in meaning to, if not synonymous with, 'stereotypical' in Putnam's definition. He implied that 'unblemished' mushrooms exist to motivate the prototype, even though the stereotypical mushroom is blemished. Cruse identified a real problem for prototype theory: What is the evidence for the well-formedness of a prototype? Consider the problem Plato identified in *Letter VII*: Perfect geometric figures cannot exist except in the mind, so if a prototypical circle is well-formed, it cannot be based on experience. Yet cognitive semantics

insists that prototypes and stereotypes are based in human experience. Hence, either the foundations of cognitive semantics are misplaced or Cruse is mistaken in suggesting that prototypes are necessarily well-formed. Let us assume that cognitive linguistics is well founded and the well-formedness criterion is wrong.

Cruse may be right in proposing a quality criterion for prototypes: A prototype is as good an example as can be found for the purpose in hand. This implies that the prototype is selected as superior to other denotata. A stereotype is not, hence the description 'typical denotatum' in Putnam's definition. How is 'a (stereo-)typical denotatum of *e*' distinguishable from 'as-good-an-exemplar-as-can-be-found among the class of things denoted by *e*'? Presumably, the stereotype properly includes the prototype. For instance, whatever the stereotype of *vegetable* may be, it properly includes the prototype carrot and the peripheral onion (Battig and Montague, 1969). The stereotypical *vehicle* includes the prototypical car and/or bus together with the peripheral horse-drawn wagon. If this is correct, then we should favor the stereotype in giving the semantics of language expressions.

What about compositionality?

(1) A blue tomato is not a tomato.

Example (1) is easily understood and a possible context for it can readily be imagined; in fact, it is conceivable that blue tomatoes can be bred. If we are to interpret *tomato* in (1) in terms of a typical denotatum, we have an incompatibility to be resolved with the color *blue*. However, there are yellow tomatoes, black tomatoes, and striped tomatoes; but, like flightless birds, they are not typical. A blue tomato, like a bearded woman, is contrary to expectation but not contrary to reason, and the phrase *blue tomato* is not contradictory and can be interpreted by analogy with *blue ball*. There are millions of things that satisfy the description *not a tomato* and certainly no prototype or stereotype for them. This is interpreted in terms of negating the typical denotatum for *tomato*.

The stereotype is a mental image, mental construct, or Gestalt with the attributes of the typical denotatum. The stereotype as the model for attributing intension (or sense) to a lexeme *e* in a lexicon should exclude connotations of *e* – these will be located in a linked encyclopedia entry. The intension (sense) of *e* has all the attributes of the typical denotatum; the recognition of the intended referent of *e* is a matter of identifying something in the world and time spoken of with characteristics that fit with the attributes of the typical denotatum of *e*.

Stokes, Whitley (1830–1909)

G Mac Eoin, National University of Ireland, Galway, Ireland

© 2006 Elsevier Ltd. All rights reserved.

Whitley Stokes was born in Dublin in 1830 to a prominent Protestant, unionist family. His father and his grandfather had been Professors of Physic (= Medicine) at Trinity College, Dublin. But they had also a strong interest in the Irish language, which was unusual at the time for people of their class; his grandfather had published translations of the New Testament in Irish around the turn of the century. In the Stokes's household congregated those who were active in the Ordnance Survey, including Charles Petrie, Eugene O'Curry, and John O'Donovan.

Stokes graduated from Trinity College with a B.A. in 1851 and then studied law in London, where he was called to the bar in 1855 and where he continued to practice until 1862. His first publication that showed an interest in Irish was a favorable review of Reeves's edition of Adomnan's *Life of Columba* (1857). By then he had met Rudolf Thomas Siegfried, a young German who had studied under Franz Bopp in Berlin and who had visited Johan Kaspar Zeuss in the last year of his life. Siegfried became Professor of Sanscrit at Trinity College, Dublin; it was he who turned Stokes's attention to Irish studies. After Siegfried died of tuberculosis in1863, Stokes gathered together his notes and drafts and published them, first in English and a few years later in German. From then until his death in 1909 there was scarcely a year in which Stokes did not publish a substantial medieval text or a number of articles on early Irish literature. His output was extraordinary, all the more so considering that he spent 19 years, from 1862 to 1881, in the British colonial service in India, far from Irish libraries and the sources from which he was working. When he returned to Ireland on vacation he spent all his time in libraries, transcribing texts, to be translated and published while he was in India.

In 1881 Stokes returned to Europe and went to live in London, continuing to work on Irish matters. While on vacation from India during the 1870s he had established a firm friendship with Ernst Windisch; this resulted in the publication of their *Irische Texte* I–V (1894–1909). Another publication of note is *Thesaurus Palaeohibernicus* (2 vols), which appeared in collaboration with John Strachan in 1901–1903. This is an edition of the Old Irish glosses, most of which had been used for the production of Zeuss's *Grammatica celtica* in 1853.

Stokes was a product of the 19th-century romantic movement. He realized that there was a need for Irish texts to appear in print as quickly as possible and supplied that need. Many of his editions are from a single manuscript, and he tended to omit the poems found in the prosimetra, considering them unworthy of attention. He allowed Kuno Meyer to use his name as a governor of the School of Irish Learning in 1903, but there is no evidence that he ever attended a meeting there. He died in 1909.

Stokoe, William (1919–2000)

M S Seegmiller, Montclair State University, Montclair, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

William C. Stokoe, Jr. (1920–2000) was an American linguist and a pioneer in the study of signed languages. He was born in New Hampshire and educated at Cornell University. Hired in 1955 to teach English at Gallaudet College (now Gallaudet University), the college for the Deaf in Washington, D.C., Stokoe became interested in the linguistic structure of American Sign Language and undertook an analysis of it. In 1960, the University of Buffalo published his book *Sign language structure: an outline of the visual communication systems of the American Deaf* (hereafter SLS), the first published work that applied the analytical techniques of linguistics to a signed language.

In SLS, Stokoe coined the term 'chereme' to denote the sign language counterpart of the phoneme. The chereme is thus the minimal unit of the linguistic system of a signed language, and morphemes can be analyzed as composed of a particular set of cheremes combined in a particular way. Cheremes can distinguish between minimal pairs, just as phonemes can. Thus, the cherology chapter in SLS mirrors the phonology chapter of a description of a spoken language.

In Stokoe's cherological analysis, each sign is made up of three elements: a sig (for signation), the motion component of the sign; a dez (for designator), the handshape component; and a tab (for tabula), the location. The chapters on morphocheremics and morphemics extend the cheremic analysis to larger units (words and morphemes) in a manner parallel to analyses of spoken languages of the time.

At the time of its publication, SLS attracted very little notice among linguists. It was more than a decade later, in the mid-1970s, before linguists began to undertake the systematic study of signed languages. The linguistic literature on signed languages is now extensive and includes analyses of many languages in addition to ASL. Although Stokoe's cheremic terminology has been discarded (it is now usual for sign language linguists to refer to the phonology of signed languages), his insights are still widely accepted, and linguists now generally agree that signed languages have the same basic structure as spoken languages.

Stokoe served as professor and chair of the English department at Gallaudet University; he was founding editor of *Sign Language Studies*, a journal devoted to the study of signed languages; and he continued a lifetime of research on signed languages and their relationship to gesture. In his final publication, *Language in hand: why sign came before speech* (2001), Stokoe argued that the gestures used by early humans evolved into signed language, which in turn gave rise to spoken languages. Thus, he claimed that the origin of all human language is to be found in signed language.

Storm, Johan (1836–1920)

E Hovdhaugen, University of Oslo, Oslo, Norway

© 2006 Elsevier Ltd. All rights reserved.

Storm was born in Lom, a rural area in the middle of Norway, where his father was a parish priest. After his father's death, Storm and his mother moved to Christiania (Oslo), where they lived under rather poor conditions, and Storm had to work as a teacher while he studied at the university. He received several scholarships to study and travel in Belgium, England, France, Italy, and Spain, and due to his special linguistic ability he learned the languages of the countries he visited with a next-to-native competence. Storm became a professor of Romance and English philology at the university in Christiania in 1873 and was thus the first professor of modern languages in Norway.

Together with Henry Sweet and Edward Sievers, Storm stressed the importance of phonetics and an articulatory–auditory approach in language teaching and language learning. Storm was a supporter of and inspiration for Sweet and Sievers when they wrote their classical introductions to phonetics, but Storm did not publish any theoretical work matching his superb practical command of phonetics. However, his introduction to English philology (1879), especially in its German translation, became a cornerstone in the university curricula of English. His *French dialogues* (1887), translated into several languages, was a milestone in the teaching of modern languages in Western Europe, focusing on giving the pupils a communicative competence in the language they were learning.

Storm put a lasting mark on Norwegian dialectology through his phonetic alphabet *Norvegia*, designed for the transcription of Norwegian dialects. *Norvegia* is quite complicated (originally with 105 symbols and later expanded to more than 150) but has until quite recently been used in the transcription of Norwegian dialects.

Another main field of research for Storm was the Norwegian language, both the spoken dialects and the literary language. His research here is marked by a vast knowledge and solid philological footwork. His studies of the phonetics of Norwegian dialects and of the stylistics of the written language are among the most important and scientific of his time. However, Storm published a number of small books and newspaper articles attacking all sides in the ongoing discussion of language planning in Norway. These publications were characterized by sharp and demagogic polemics and a negative attitude toward language planning, new norms, and their creators. This made him unpopular almost everywhere, and few read and took notice of his scholarly publications on Norwegian.

Strachan, John (1862–1907)

G Mac Eoin, National University of Ireland, Galway, Ireland

© 2006 Elsevier Ltd. All rights reserved.

John Strachan was a Scotsman, born in Banffshire to a farming family on January 31, 1862. He graduated in classics from the University of Aberdeen in 1881. He spent 1883 at the University of Jena, where he came under the influence of Rudolf Thurneysen. Strachan acquired from Thurneysen an interest in linguistics, and, most significantly, in Celtic studies. Strachan was appointed professor of Greek at the University of Manchester in 1885, and the duties of this post were extended in 1889 to include comparative linguistics. But his interest lay mainly in Celtic studies. He was appointed lecturer in Celtic (an unpaid post) and he founded the first School of Celtic Studies in Britain. From 1887, he began to publish on Latin and Greek philology and particularly on Celtic matters; at first short notes, but by 1892 extending to longer contributions, such as 'The compensatory

Strachan, John (1862–1907)

G Mac Eoin, National University of Ireland, Galway, Ireland

© 2006 Elsevier Ltd. All rights reserved.

John Strachan was a Scotsman, born in Banffshire to a farming family on January 31, 1862. He graduated in classics from the University of Aberdeen in 1881. He spent 1883 at the University of Jena, where he came under the influence of Rudolf Thurneysen. Strachan acquired from Thurneysen an interest in linguistics, and, most significantly, in Celtic studies. Strachan was appointed professor of Greek at the University of Manchester in 1885, and the duties of this post were extended in 1889 to include comparative linguistics. But his interest lay mainly in Celtic studies. He was appointed lecturer in Celtic (an unpaid post) and he founded the first School of Celtic Studies in Britain. From 1887, he began to publish on Latin and Greek philology and particularly on Celtic matters; at first short notes, but by 1892 extending to longer contributions, such as 'The compensatory

lengthening of vowels in Irish' (1892), 'The history of the deponent verb in Irish' (1894), 'The verbal system of Saltair na Rann' (1895), 'The use of the particle *ro-* with preterital tenses' (1896), 'The uses of the subjunctive mood in Irish' (1897), and 'The substantive verb in the Old Irish glosses' (1899). From 1901 to 1903, in collaboration with Whitley Stokes, he produced *Thesaurus palaeohibernicus* in two volumes (1901–1903), a collection of Old Irish glosses and other material with lemmata and translations from manuscripts in European libraries. From 1903 until his death, he participated in the work of the School of Irish Learning, founded by Kuno Meyer and himself in Dublin, lecturing on Old Irish and providing textbooks for the students, *Stories from the Táin* (1903), *Selections from the Old-Irish glosses with notes and vocabulary* (1904), and *Old-Irish paradigms* (1905). He had written a grammar of Middle Welsh, which was published as *Introduction to Early Welsh* (1909), and included a Middle Welsh reader. This was prepared for the press by Kuno Meyer and published posthumously at Manchester. In those last years, he continued to publish on Celtic, Indo–European, and Greek matters. He contributed to many periodicals, foremost among which was *Ériu*, the publication of the School of Irish Learning, which he edited with Meyer and to which he gave its name. In September 1907, he went to Peniarth, Merioneth, to check manuscripts and caught pneumonia from sleeping in a damp bed; he died on September 25. Today his work is still highly regarded as solving many problems of medieval Irish grammar, except for the meaning of Old Irish *ro-* before a preterite, which he got wrong. His textbooks, particularly his *Old Irish paradigms and glosses* (as revised by Osborn Bergin, combining Strachan's publications on the glosses and the grammar) and *Stories from the Táin*, are still used in introducing students to Old Irish. According to those who attended his classes, he was an energetic and inspiring lecturer, patient and kind with his students, with quiet but genial humor. There was a complete list of his publications, compiled by Kuno Meyer, in *Ériu 3* (1907: 202–206).

Peter Frederick Strawson was born on November 23, 1919, in Ealing, a London suburb. He attended Christ's College at Finchley and graduated from the University of Oxford in 1940. That summer he was called up and served in the Royal Artillery until 1946, attaining the rank of captain. He then became Assistant Lecturer in Philosophy at the University College of North Wales in Bangor. In 1947, he became a philosophy tutor at Oxford and from 1948 to 1968 served as Fellow and Praelector in Philosophy at the University College, Oxford. He was elected to the British Academy in 1960. In 1968, he became Fellow of Magdalen College and Waynflete Professor of Metaphysical Philosophy at Oxford. He was knighted in 1977, becoming Sir Peter Frederick Strawson. In 1987, he retired from his Chair and became a professor emeritus to continue his academic travels, lecturing, and writing.

Strawson's important contributions to the study of language, philosophy, and linguistics have concerned meaning and reference. He approached this problem

lengthening of vowels in Irish' (1892), 'The history of the deponent verb in Irish' (1894), 'The verbal system of Saltair na Rann' (1895), 'The use of the particle *ro-* with preterital tenses' (1896), 'The uses of the subjunctive mood in Irish' (1897), and 'The substantive verb in the Old Irish glosses' (1899). Peter Frederick Strawson was born on November 23, 1919, in Ealing, a London suburb. He attended Christ's College at Finchley and graduated from the University of Oxford in 1940. That summer he was called up and served in the Royal Artillery until 1946, attaining the rank of captain. He then became Assistant Lecturer in Philosophy at the University College of North Wales in Bangor. In 1947, he became a philosophy tutor at Oxford and from 1948 to 1968 served as Fellow and Praelector in Philosophy at the University College, Oxford. He was elected to the British Academy in 1960. In 1968, he became Fellow of Magdalen College and Waynflete Professor of Metaphysical Philosophy at Oxford. He was knighted in 1977, becoming Sir Peter Frederick Strawson. In 1987, he retired from his Chair and became a professor emeritus to continue his academic travels, lecturing, and writing.

Strawson's important contributions to the study of language, philosophy, and linguistics have concerned meaning and reference. He approached this problem

from a more empirical perspective than was common among the so-called 'ideal' language philosophers that preceded him. He would become known as one of the premier 'ordinary' language philosophers, along with Gilbert Ryle and J. L. Austin. In his article 'On referring' (1950), Strawson challenged Bertrand Russell's theory of definite descriptions. Strawson argued (1959, 1971, 1992) that material bodies of things and persons are essential to determining the meanings of social speech acts of referring, while Russell (1914) held that things and persons, though perhaps real, cannot be sufficiently grounded for us even to know for certain that they exist. Strawson, by contrast, insisted that things, persons, and events form a kind of basic material in space and time in which symbol systems of language must be grounded. In this argument, Strawson anticipated major themes in linguistics (Lakoff and Johnson, 1999), discourse processing (Glenberg and Robertson, 1999; Roth and Lawless, 2002), perceptual symbol theory (Barsalou, 1999), situational semantics (Barwise and Perry, 1983), conversational analysis (Hindmarsh and Heath, 2003; Streeck, 1996), and general semiotic theory (Oller *et al.*, 2005).

Strawson argued that a fact is not an independent entity that can be identified without the assistance of a proposition. Rather, a fact is merely what is asserted by a true statement. Strawson disputed on this basis the variety of the 'correspondence theory of truth' attributed to positivists such as Tarski (1936/1956). In noting the conceptual nature of facts, as determined by propositional statements, Strawson concurred with C. S. Peirce (1897), who had pointed out that no fact can be singled out for any special attention at all without some means of distinctly representing that fact. Raw facts have no power to identify themselves independently at all. Thus, Strawson was among the first to show that a strict situational semantics driven by raw facts cannot work. On the other hand, Strawson's position also refuted the opposing extreme of those who have attempted to cut representations entirely loose from any moorings to material bodily entities in the space time world, e.g., the early and later theories of syntactic autonomy (Chomsky, 1965; Jackendoff, 1997).

In his work on individuals, Strawson argued that material entities situated in space and time are crucial not only to our being able to define our own identities but also to the possibility of discovering (fixing) the conventional meanings of abstract symbols. While his arguments do not aim for the generality and exactness sought by C. S. Peirce, Strawson independently showed that material entities in space and time are basic and prerequisite to language systems. Although the implications of Strawson's theory of reference have certainly not been universally accepted, his emphasis on linguistic acts as performatives that bear presuppositional weight has had widespread impact. It resonates in the work of ordinary language philosophers, linguists, psychologists, ethnographers, and empiricist of all stripes. The name 'P. F. Strawson' is so closely associated with 'speech act theory' that it is commonly mentioned along with J. L. Austin and John Searle. Strawson also incidentally encouraged the closer investigation of discursive behaviors from a psychological, linguistic, and ethnographic point of view.

Stroop Effect in Language

C M MacLeod, University of Waterloo, Waterloo, Ontario, Canada

The Stroop Task and its Potential for Studying Language

The Stroop effect is the best known phenomenon in cognitive psychology, and may well be the best known phenomenon in all of psychology. In his dissertation, John Ridley Stroop (for a biography, see MacLeod, 1991b) first reported the paradigm that now bears his name (Stroop, 1935). Since then, thousands of studies have employed this task and its variants to study theoretically interesting aspects of attention, learning, memory, and language (see MacLeod, 1991a, for a comprehensive review). The task has also seen widespread use in neuropsychology, for diagnosing attentional problems, and in clinical psychology, for studying anxieties.

The task itself is deceptively simple: you must name the color in which something is printed as fast as possible, the dependent measure being color-naming response time (RT). The key is what the 'something' is – the carrier of the color that must be ignored while you name the color. In his first experiment, Stroop (1935) showed that we can read a word aloud as quickly when it is printed in an incompatible color (the incongruent condition) as when it is printed in familiar black ink (the control condition). Thus, saying 'green' to the word *green* printed in red ink was no slower than when *green* was printed in black. His second experiment was the critical one: here he showed that naming the ink color was dramatically slower for the incongruent condition than for the case where there was no color word at all (the control condition). Thus, saying 'red' to the word *green* printed in red was markedly slower than saying 'red' to a red color patch.

The extra time to name the color when there is an incompatible word present (i.e., the RT difference between the incongruent and control conditions) is known as the Stroop effect, or Stroop interference. This observation would perhaps simply have been seen as an intellectual curiosity were it not for the fact that interference is observed even when the irrelevant item is not a color word. Klein (1964) first made this point by showing a gradient of declining interference as the to-be-ignored words progressively changed from color words (e.g., *blue*) to color-related words (e.g., *sky*) to high frequency words (e.g., *friend*) to low frequency words (e.g., *abjure*) to nonwords (e.g., *evgjc*). Klein's observation opened up the task for use as an indirect measure of word activation. **Figure 1** illustrates several of these conditions, including the congruent condition (introduced later), where facilitation (faster RT than in the control condition) is often observed.

Figure 1 Illustrations of different types of to-be-ignored verbal items in the color-word Stroop task. The task is always to name the print color. The columns indicate (1) unpronounceable nonword letter strings, (2) pronounceable nonwords, (3) high frequency noncolor words, (4) the classic incongruent color words, and (5) the congruent case, where word and color match. Try naming the colors down each column as quickly as possible, being careful not to read the verbal items. You should notice more difficulty (interference) as you move from the first to the fourth column, and then a noticeable easing (facilitation) in the fifth column.

The Stroop Task and its Potential for Studying Language

The Stroop effect is the best known phenomenon in cognitive psychology, and may well be the best known phenomenon in all of psychology. In his dissertation, John Ridley Stroop (for a biography, see MacLeod, 1991b) first reported the paradigm that now bears his name (Stroop, 1935). Since then, thousands of studies have employed this task and its variants to study theoretically interesting aspects of attention, learning, memory, and language (see MacLeod, 1991a, for a comprehensive review). The task has also seen widespread use in neuropsychology, for diagnosing attentional problems, and in clinical psychology, for studying anxieties.

The task itself is deceptively simple: you must name the color in which something is printed as fast as possible, the dependent measure being color-naming response time (RT). The key is what the 'something' is – the carrier of the color that must be ignored while you name the color. In his first experiment, Stroop (1935) showed that we can read a word aloud as quickly when it is printed in an incompatible color (the incongruent condition) as when it is printed in familiar black ink (the control condition). Thus, saying 'green' to the word *green* printed in red ink was no slower than when *green* was printed in black. His second experiment was the critical one: here he showed that naming the ink color was dramatically slower for the incongruent condition than for the case where there was no color word at all (the control condition). Thus, saying 'red' to the word *green* printed in red was markedly slower than saying 'red' to a red color patch.

The extra time to name the color when there is an incompatible word present (i.e., the RT difference between the incongruent and control conditions) is known as the Stroop effect, or Stroop interference. This observation would perhaps simply have been seen as an intellectual curiosity were it not for the fact that interference is observed even when the irrelevant item is not a color word. Klein (1964) first made this point by showing a gradient of declining interference as the to-be-ignored words progressively changed from color words (e.g., *blue*) to color-related words (e.g., *sky*) to high frequency words (e.g., *friend*) to low frequency words (e.g., *abjure*) to nonwords (e.g., *evgjc*). Klein's observation opened up the task for use as an indirect measure of word activation. Figure 1 illustrates several of these conditions, including the congruent condition (introduced later), where facilitation (faster RT than in the control condition) is often observed.

Figure 1 Illustrations of different types of to-be-ignored verbal items in the color-word Stroop task. The task is always to name the print color. The columns indicate (1) unpronounceable nonword letter strings, (2) pronounceable nonwords, (3) high frequency noncolor words, (4) the classic incongruent color words, and (5) the congruent case, where word and color match. Try naming the colors down each column as quickly as possible, being careful not to read the verbal items. You should notice more difficulty (interference) as you move from the first to the fourth column, and then a noticeable easing (facilitation) in the fifth column.

Figure 2 Illustrations of some of the possible conditions in the picture-word task. The task is always to name the picture, ignoring the word. Shown from left to right are an incongruent condition, a semantically related condition, a congruent condition, and a control condition. Interference would be expected for the first two and facilitation for the third, all relative to the fourth (control) condition.

The next step in demonstrating that the Stroop task provides a general way to evaluate ongoing processing was to demonstrate priming in the task. Warren (1972) showed that if a target word to be color named was preceded by related words, then the interference exerted by the target word was reliably increased. As an illustration, if 'elm,' 'oak,' and 'maple' were presented auditorily prior to *oak* in red, then time to say 'red' was slower than for prime words unrelated to the critical target word. This is evidence of identity or repetition priming; perhaps more impressive was his finding that semantic priming – the target was now *tree* in red – also produced substantially increased interference in naming the target's color.

There is one more piece of the puzzle required for use of the Stroop task to study language. In many language-relevant situations, the limited stimulus set of the standard Stroop task – a few colors and their names – poses a significant impediment. Cognitive psychologists have created many task variants (see MacLeod, 1991b), but one has been particularly pivotal in the domain of language: the picture-word task (see, e.g., Lupker, 1979). Here, line drawing pictures are presented in the presence of a word, with the word to be ignored and the picture to be named. Figure 2 illustrates four key conditions using this paradigm, although others are possible. This task has been used widely in language research, and there are now extensive picture-naming norms available (see Szekely *et al.*, 2004).

Using the Stroop Task to Study Language

Klein's (1964) and Warren's (1972) studies gave rise to a veritable cottage industry of color-word and picture-word interference studies aimed at issues central to understanding language, from sound to meaning. This section provides pointers to language-relevant research using the Stroop task.

Word Sound and Form

Early on, Dalrymple-Alford (1972b) demonstrated that when a competing color name was primed acoustically, both types of acoustic relation – initial sound (e.g., *run* for *red*) and terminal sound (*clean* for *green*) – caused interference, although considerably less than actual color words. Note that even just first letters of competing color names (e.g., *r* in green) produce reliable interference, possibly implicating an articulatory component (Regan, 1978).

Tanenhaus *et al.* (1980) showed that if the prime was related orthographically or phonologically, or both, to the irrelevant target word, interference was greater than for unrelated primes. This generalized to both auditorily and visually presented primes. In the picture-word task, Lupker (1982) found that either orthographic or phonemic similarity between the word and the picture's name led to facilitation relative to a nonword, a benefit that he attributed to decreased retrieval time for the picture name. Besner and Stolz (1998) used interference from pseudohomophones (e.g., *bloo*) to argue that a phonological code is routinely computed. Burt (2002) has demonstrated that activation of the identical word via priming produces facilitation but activation of a related word produces interference, arguing that activating competing phonologies plays a role in interference.

Syntax and Part of Speech

Using the picture-word task, Ehri (1977) showed that nouns interfered more than adjectives or functors, suggesting to him that interference was not phonologically based. Pechmann and Zerbst (2002) confirmed this result in the picture-word task, arguing that syntactic and semantic processing overlap early in lexical processing. Taken together with the preceding discussion on phonology, a better suggestion would appear to be that multiple factors contribute to the interference – that it is not readily localized at one level of linguistic analysis. There is little work on syntax and interference, but Schriefers (1993) has shown in Dutch that a difference in noun gender between the word and the picture increases interference.

Semantics

The bulk of the action in linguistic studies using the Stroop task and its analogs has been in the domain of meaning, in line with the Klein (1964) and Warren (1972) studies. Dalrymple-Alford (1972a) confirmed Klein's finding that color-related words interfere more than non-color-related words, but not as much as color words, so relation to color is important in degree of interference. Klein's word frequency

finding, that high-frequency words interfere more than low-frequency words, has been complicated by Burt (2002), who finds the opposite pattern when the words are primed. And in the picture-word task, nonwords also cause less interference than words (e.g., Lupker, 1982). Oddly, whereas an associated word interferes more than an unrelated word with color naming, this does not appear to be the case in the picture-word task. Yet a categorically related word does interfere more than an unrelated word (Golinkoff and Rosinski, 1976). There may well be fundamental differences between these two tasks, a direction for future research.

Possibly the most dramatic meaning effects in the Stroop task have come from research in clinical psychology, and a phenomenon now widely called the emotional Stroop effect. C. MacLeod (2005) describes a large body of research in which personally meaningful concepts can produce enhanced priming. Thus, for example, an arachnophobe shows heightened RT to name the colors of spider-related as opposed to neutral words (Watts *et al*., 1986). Even the threatening of larger beliefs, such as belief in a just world, can enhance interference in color naming of justice-related words (Hafer, 2000). Quite clearly, the Stroop task is extremely sensitive to meaning, whether primed or not.

Bilingualism

There is also a considerable body of Stroop interference evidence relevant to people who speak more than one language. Preston and Lambert (1969) found quite strong interference whether bilinguals had to name the ink colors in the same language as the distracting words or in the other language. Across a fairly large set of studies, a reasonable overall estimate of cross-language interference would be from 66–75% of that within language. Although interference between languages can sometimes be as great as that within languages, this clearly depends on relative familiarity with the two languages in question (Mägiste, 1984).

Beyond the Word

Conrad (1974) was the first to investigate sentence materials in the context of the Stroop task, showing that both meanings of an ambiguous word (e.g., *nickel*) were activated in processing a sentence such as *That nickel is from her coin collection*. She demonstrated this by showing that either the word *metal* or the word *money* interfered with color naming equally, despite only the latter sense being consistent with the sentence. Later work has shown that initial activation may be similar but that, if a time interval is inserted between the sentence and the target, the appropriate word soon wins out and only that word will produce interference.

As another illustration of sentence-level processing, Whitney and Kellas (1984) presented sentences that biased a typical category member (e.g., *The guest saw the bird that landed on the branch – robin*) or an atypical member (e.g., *The guest saw the bird that roasted on the grill – chicken*) vs. a neutral sentence. Regardless of the prime sentence, the typical word always caused interference, whereas the atypical word did not. Other work by Whitney extended this kind of pattern to anaphoric reference. Studies of this form have become frequent in the literature for examining the activation of conceptual language-based information (see MacLeod, 1991a).

Theories of Stroop Interference

Early theories of the processes involved in producing Stroop interference tended to focus on the speed of processing – that words were faster to process for naming than were colors (or pictures), an idea that goes back to Cattell (1886) at the dawn of psychology. This readily accounted for the asymmetry that words interfere with color naming but colors do not interfere with reading, and fit well with Cattell's proposal that word reading became automatic through extensive practice.

Cohen *et al*. (1990) realized this automaticity idea in terms of a formal connectionist model where connection strengths determined by learning produced interference. More recently, Melara and Algom (2003) have argued that discriminability along the two dimensions – word and color – underlies the performance pattern, presenting a formal model based on this notion. In a psycholinguistic vein, Roelofs (2003) has extended the WEAVER++ model of word production to the case of Stroop interference. All of these theories have been quite successful in handling the rich database that now exists on the Stroop effect, a database running from simple behavioral experiments to complex psycholinguistic studies to new work on brain structures involved in interference (see MacLeod and MacDonald, 2000).

Conclusion

The Stroop task provides a valuable tool for understanding how words and more extended linguistic elements are processed and understood. It is generally simple to do a Stroop experiment (for coverage of methodological issues, see C. M. MacLeod, 2005), and the many task variations simultaneously permit flexibility and generalizability.

What is especially appealing about the Stroop task for cognitive psychologists and psycholinguists is its status as an **indirect** measure of language processing. The individual being tested is to name the color or picture, and is expressly not to read the word. So if the word interferes with naming the color or picture, this is seen as not being a strategic effect, given that the individual is trying to ignore the word. To the extent that the interference varies as a function of some manipulation, this can then be taken to index the degree of processing of the verbal material without the biases that appear to be more possible in a direct measure of word processing, such as lexical decision or speeded reading (naming). At the age of 70, the Stroop effect is still going strong.

Structuralism

B Clark, Middlesex University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The term 'structuralism' can be applied to a wide range of approaches in linguistics and in other areas. Each variety of structuralism has its origins in the work of Ferdinand de Saussure, as presented in the *Cours de linguistique générale* (Saussure, 1972, 1983) which was originally published posthumously in 1916. Within linguistics, virtually all approaches are structuralist in that they are concerned with the workings of a linguistic system. However, 'structuralism' is usually taken to refer to a range of approaches which were developed in the first half of the 20th century and largely abandoned following the development of Chomskyan 'generative' linguistics. Outside linguistics, 'structuralism' refers to a more diverse range of approaches in a wide range of fields, including anthropology and literary criticism, which propose explanations of texts, behaviors, and cultural phenomena in terms of a structured system of oppositions, contrasts, and hierarchies.

Structuralism in General

The key property that makes an approach 'structuralist' is that it considers phenomena as **systems**, or the products of systems, rather than as collections of isolated items or in terms of their history.

Many different phenomena have been approached in structuralist terms, but the origin of the notion is in Saussure's approach to the study of language. Features taken to be typical of structuralism appeared in the work of some of Saussure's predecessors and contemporaries, and Saussure never used the terms 'structuralist' or 'structuralism' in his own work. Nevertheless, the work that has been by far the most influential in the development of structuralism is Saussure's posthumously published *Cours de linguistique générale* (Saussure 1972, 1983). This work was not authored by Saussure but compiled from the lecture notes of students who attended the third of three series of lectures given by Saussure in Geneva between 1906 and 1911.

Saussure divided '*langage,*' the whole of language, into '*langue*' and '*parole*' and identified langue as the focus of linguistic study. He made a distinction between diachronic (i.e., historical) studies, which compare langue at different points in time, and synchronic studies, which study langue at one particular point in time. Perhaps the most important observations he made about langue were, first, that there was an arbitrary connection between linguistic signs and what they represent and, second, that the value of a particular unit within the system depends on its opposition to, or how it contrasts with, other units within the system. For example, there is no reason other than historical accident why the English word for a young female human should be *girl* while the French word for the same concept should be *fille*. Further, the existence of the terms *boy* in English and *garçon* in French are required in order for *girl* and *fille* to have the values they do.

Within linguistics, these notions led to a focus on language systems at a particular moment in time (alongside ongoing work on the historical development of languages). Beyond linguistics, it led to the search for similar systems in other areas.

Structuralism outside Linguistics

A wide range of broadly structuralist approaches have been developed in fields such as anthropology, art and literary criticism, biology, ethnology, mathematics, media studies, psychoanalysis, psychology, and sociology. Each of these begins by attempting to analyze the systems of oppositions, contrasts, and hierarchical structures underlying the meanings of the phenomena being studied. In anthropology, for example, Lévi-Strauss aimed to develop a scientific approach to anthropology based on structuralist ideas. His first book (Lévi-Strauss, 1949) proposed an analysis of kinship based on an underlying system of structuralist oppositions. In literary criticism, analyses of literary meanings were based on the assumption that literary texts implied sets of structural oppositions. Texts could then be viewed as similar or distinct based on the underlying structures they implied. Roland Barthes (1957) and others proposed

Structuralism in General

The key property that makes an approach 'structuralist' is that it considers phenomena as **systems**, or the products of systems, rather than as collections of isolated items or in terms of their history.

Many different phenomena have been approached in structuralist terms, but the origin of the notion is in Saussure's approach to the study of language. Features taken to be typical of structuralism appeared in the work of some of Saussure's predecessors and contemporaries, and Saussure never used the terms 'structuralist' or 'structuralism' in his own work. Nevertheless, the work that has been by far the most influential in the development of structuralism is Saussure's posthumously published *Cours de linguistique générale* (Saussure 1972, 1983). This work was not authored by Saussure but compiled from the lecture notes of students who attended the third of three series of lectures given by Saussure in Geneva between 1906 and 1911.

Saussure divided '*langage,*' the whole of language, into '*langue*' and '*parole*' and identified langue as the focus of linguistic study. He made a distinction between diachronic (i.e., historical) studies, which compare langue at different points in time, and synchronic studies, which study langue at one particular point in time. Perhaps the most important observations he made about langue were, first, that there was an arbitrary connection between linguistic signs and what they represent and, second, that the value of a particular unit within the system depends on its opposition to, or how it contrasts with, other units within the system. For example, there is no reason other than historical accident why the English word for a young female human should be *girl* while the French word for the same concept should be *fille*. Further, the existence of the terms *boy* in English and *garçon* in French are required in order for *girl* and *fille* to have the values they do.

Within linguistics, these notions led to a focus on language systems at a particular moment in time (alongside ongoing work on the historical development of languages). Beyond linguistics, it led to the search for similar systems in other areas.

Structuralism outside Linguistics

A wide range of broadly structuralist approaches have been developed in fields such as anthropology, art and literary criticism, biology, ethnology, mathematics, media studies, psychoanalysis, psychology, and sociology. Each of these begins by attempting to analyze the systems of oppositions, contrasts, and hierarchical structures underlying the meanings of the phenomena being studied. In anthropology, for example, Lévi-Strauss aimed to develop a scientific approach to anthropology based on structuralist ideas. His first book (Lévi-Strauss, 1949) proposed an analysis of kinship based on an underlying system of structuralist oppositions. In literary criticism, analyses of literary meanings were based on the assumption that literary texts implied sets of structural oppositions. Texts could then be viewed as similar or distinct based on the underlying structures they implied. Roland Barthes (1957) and others proposed

analyses of cultural and artistic concepts in structuralist terms, and a new general field of semiotics was developed (Eco, 1976). Much of this work was inspired by the suggestion in the *Cours* that linguistics would eventually be seen as one part of a new science of *semiology*, concerned with the general study of signs. The more recent developments of poststructuralism and deconstruction can be seen simultaneously as both developments and rejections of earlier versions of structuralism. Many of these approaches diverged greatly from developments in linguistics, which retained their focus on the **linguistic** system.

Structuralism within Linguistics

A number of schools of linguistics in the early 20th century built on Saussure's ideas. These included: the Geneva school, where Saussure's ideas continued to be developed for at least three generations; the Copenhagen Linguistics Circle, associated with Hjelmslev's glossematics; Firthian contextualism in London; the Prague School, most famously associated with the work of Trubetskoy, Jakobson, and Martinet; and American Structuralism as developed by Bloomfield, Sapir, and others.

It is often assumed that structuralism came to an end when Chomsky published *Syntactic Structures* in 1957. But Chomsky rejected specific aspects of American (perhaps even more specifically Bloomfieldian) structuralism, in particular the focus on 'surface' forms rather than the underlying cognitive system and the 'taxonomic' approach which aimed to describe languages rather than explain them. Bloomfield aimed to develop a **scientific** approach and his benchmark for scientific methodology was behaviorism, which denied reference to the mind, or mental entities. Chomsky pointed out the extent to which behaviorist explanations were vacuous and that there was considerable evidence for a system of knowledge underlying linguistic behavior. Chomsky also rejected Bloomfield's notion that the careful use of 'discovery procedures' would ensure that linguistics was an objective, empirical science. He argued that strong and clear evidence about the linguistic system could be provided by the intuitions of speakers.

While Chomsky rejected significant aspects of American structuralism, his work and that of later linguists has built on a number of insights provided by structuralists. Chomskyan linguists do not question the value of descriptive work and the descriptive work of structuralists provided a large amount of useful data. Rather, they believe that it is important to go further and to look also for explanations of linguistic phenomena. Some work in the Chomskyan tradition is a development of the work of structuralist linguistics. For example, Chomsky's own work with Morris Halle (Chomsky and Halle, 1968), which analyzed the English phonological system in terms of a number of distinctive features, can be seen as a development of the Prague School work on phonology, which analyzed the sound systems of languages in terms of a series of contrasts. Structuralist linguistics is often assumed to be of only historical interest. But it has left its imprint on more recent work in more than the fairly vacuous sense in which most, if not all, approaches to linguistics assume the existence of a linguistic system.

Structuralism in Anthropology

R Stasch, Reed College, Portland, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Structuralism in anthropology is the view that meaning in human sociocultural life rests in the positional configuration of elements relative to each other in a structure or system, not in properties of those elements considered in their own right, nor in the elements' ties to forces external to the system. Various modern anthropologists have set forth partly structuralist theories and methodologies, including Sapir (e.g., 1949), other linguistically-oriented Americanists, and Dutch colonial scholars working in the Malay archipelago (de Josselin de Jong, 1977). However, structuralist anthropology as a paradigm is most associated with Claude Lévi-Strauss, who formulated and practiced it from the 1940s onward as an avowed adaptation of linguistic models of phonological order. Structuralism was one of the most influential intellectual movements in the human sciences and humanities in the 20th century.

Lévi-Strauss's Transfer of an Idea from Phonology to Analysis of Culture

Lévi-Strauss's initial exposure to structural linguistics came in the early 1940s, when he attended lectures in which Roman Jakobson outlined phonemes' character as negative, relative positions in a language-specific total configuration of significant distinctions (Jakobson, 1978). The model of language Lévi-Strauss thus acquired was that of *langue* or "linguistic system" set forth by Saussure (1959). In the lectures, Jakobson emphasized the uniqueness of phonological signs, as the only linguistic signs that are purely differential and negative in the Saussurean manner. Linguistic signs of all other levels possess characteristics and functions that are not determined exclusively by their position in a system of other signifiers. Far from heeding this point, Lévi-Strauss saw the phonological model to be directly useful in deepening anthropological understanding of vast areas of human sociocultural life beyond linguistic codes.

Lévi-Strauss applied metaphorically phonological styles of analysis to hundreds of anthropological subjects. Bending the '+' and '−' formalism of feature analysis to characterize whole social relationships, he suggested that in particular societies the moral and emotional quality of ties between different categories of kin is not determined by those kin relations in themselves but by their place in a configuration of other relations (Lévi-Strauss, 1963a). He similarly argued that the categorization of particular kinds of relatives as marriageable and others as unmarriageable (such as the common pattern of categorizing children of a brother and sister as marriageable 'cousins' while categorizing the children of same-sex siblings as unmarriageable 'siblings') in a given society instantiates a society-level distribution of significant distinctions, and that a commitment to relations as such (in the form of a principle of reciprocity, or dependency on others for spouses) is the raison d'être of distinct kin categories and of marriage rules (Lévi-Strauss, 1969a). Regarding totemism (Lévi-Strauss, 1963b), he argued that the point of animal symbols is not the characteristics or usefulness of particular species but their intellectual value as signifiers of relational distinctness itself. Humans look to the distinctness of animal species for analogic markers of social distinction. Generalizing this argument in *The savage mind* (1966), Lévi-Strauss sought to document a pan-human faculty of proliferating classificatory order in relation to all concrete things and qualities in the world, through analogic mapping between sets of categorial distinctions. In numerous works on myth (e.g., Lévi-Strauss, 1969b), he argued that at multiple scales mythological narratives are elaborately organized around basic categorial oppositions between minimal signifying elements (termed mythemes).

Structuralism's Influence in Anthropology

Lévi-Strauss's main ideas, and his work on specific empirical topics, prompted a deepening of anthropologists' imaginativeness in noting interconnections across heterogeneous cultural data. Minimally, structuralism is the heuristic premise that all phenomena in cultural worlds might be interrelated, and that patterning of form (convergences in the shape or position of cultural elements, even in the absence of reflexive commentary about those elements on the part of the people practicing them) is itself evidence of such interrelatedness because it is a basic mode in which interrelatedness exists. This notion was intrinsic to pre-World War II anthropology's emergent understandings of culture (following Boas) or social order (following Durkheim), but Lévi-Strauss's structuralism pushed anthropology further in presenting an explicit alternative to the commonsense ideology that conscious individual psychology is the basic determinant of cultural practices. Even as scholars found serious fault with many of Lévi-Strauss's specific empirical claims and interpretive idioms, in the wake of structuralism it has become routine for

anthropologists to identify far-reaching, nonobvious patterns of interconnection across narratives, rituals, architectural forms, practices of food production and consumption, practices of bodily adornment, geography, cosmology, and other areas of life, where formerly these areas might have been only subjects of descriptive cataloguing. Structuralism gave anthropology new reach in seeing abstract categories or principles in ethnographic particulars. The anthropological topic of taboo, for example, was substantially reconceived following Lévi-Strauss's work on classification, when Leach (1964) and Douglas (1966) proposed structuralist analyses of taboos as enforcing the distinctness of categories in a culturally given system by suppressing interstitial entities, such as taxonomically anomalous animals. Recognition of symbolic logics at work in taboos of particular communities has been central to most subsequent writing on the subject.

Yet absorption of some of structuralism's broad methodological insights has been matched also by emphatic rejections of structuralism as an overall theoretical doctrine in many anthropological quarters. The reasons for this include succession of intellectual generations, resurgence of ideologies of individualism, susceptibility of a famous body of work to stereotypic simplification, and continuing credence given to anthropological theories that do not recognize signification as a universal aspect of human activity. Among anthropologists who do recognize signification as basic to their subject, another influence of structuralism has been its enduring relevance as a foil against which to define other theoretical possibilities.

Errors in the Thesis of Autonomous System

Structuralism's central thesis is the autonomy of system, or the notion that a system of cultural categories is self-identical and self-determining. A system determines its internal elements, and is not determined by them. It is not affected by elements, forces, or systems outside itself, nor does it produce gaps of absent or contrary determination within itself. This autonomy and self-sameness of system is axiomatic to structuralism's methodological prescription of searching out the positional value of cultural elements. An element has a unitary positional value in relation to a set of other elements only to the same degree that there is a single stable and definably bounded system within which that element is embedded (though Lévi-Strauss's own unit of study was often the system of human culture at large). The thesis of the autonomy of system has its *locus classicus* in Saussure's definition of *langue* or "language system, grammar, code." Saussure axiomatically separated linguistic system from language use, from temporality, from system-independent characteristics (e.g., materiality) of the media of signification and of the objects signified, and from the possibility of the simultaneous coexistence of different systems.

To summarize the full range of ways that anthropologists have pushed off from structuralism would probably be to summarize the state of the entire discipline. All currently important theoretical frameworks, though, have in common that they depart from the thesis of autonomous system by recognizing any given structural system to be foundationally dependent on and involved with something other than itself. In various ways, these departures from structuralism turn 'system' or 'structure' into a question rather than a premise.

The most frequent focus of revision has been system's involvement with history and events. Most scholars understand structuralism to be ahistorical. Saussure identified linguistic system as a synchronic phenomenon, existing virtually as if in a slice of time rather than diachronically as an entity whose internal makeup might be inseparable from its having histories and futures different from its present. Saussure further abstracted temporality out of structure by distinguishing *langue* "system, grammar" from *parole* "speech, performance, use." This distinction imagines that structures exist autonomously of events, such as events of signification in which speakers practice structural forms. There is a line of influence from these Saussurean axioms to Lévi-Strauss's views that myths are "instruments for the obliteration of time" or that some societies are culturally oriented to resisting structure-perturbing effects of events. Anthropologists in their empirical work have generally found, however, that all human sociocultural forms are inherently temporal and historical, in various senses. The forms change in time. Sahlins (1985), Robbins (2004), and others have presented structuralist-historical case studies arguing that discernment of broadly Saussurean cultural structures is itself crucial to account for processes of sociocultural transformation. Many scholars have found that system-internal relations at a given time are insufficient to give an account of how a system works or how it is what it is, but rather that its history is a necessary element of a scholarly understanding of that system, in many cases because the cultural forms themselves are internally diachronic and open-ended. If it is recognized that structures exist at a particular present moment temporally rather than virtually, this raises questions such as: How big is the present? What are the ways that a particular 'present' is inherently intertemporal, in the

sense of being connected to and composed of past and future moments that are different from it?

Considerations of temporality are inseparable from considerations of a wider array of ways structure is irreducibly involved with subjectivity and with use-in-context, including sign users' reflexive orientations to their sign systems and signifying practices. The force of Lévi-Strauss's adoption of phonology as a metaphor for culture was to emphasize the nonconscious character of structures. Just as people speak without having overt propositional knowledge of their language's grammatical structures, so too cultural subjects' consciousness (or indeed, their existence) is secondary to the cultural structures in which they live, and may have no necessary place in analysis of those structures. Yet in linguistics, Benveniste (1971) showed that first- and second-person pronouns are elements of linguistic structure that encode the presence of a speaking or listening subject, and Jakobson (e.g., 1971) elaborated this point for the encoding of diverse aspects of a situation of speech use in grammatical shifters. This amounts to recognizing *parole* as irreducibly present in *langue*. In diverse ways, anthropologists have found the perspectives of acting subjects to be integral to cultural structure, often, though, also finding that the relations between structure and subject, between these two and material or institutional worlds, or even between a subject and itself, are not seamless. For example, Valeri (2000) documents tensions between symbolic logic and mortal, bodily conditions of existence underpinning the taboos of a hunting community. Relatedly, scholars have sought in varying ways and with varying success to reconcile perceptions of categorial structure with social dynamics of value, hierarchy (Dumont, 1980), power, and desire. Work in linguistic anthropology documents the structure-creating effects of pragmatic acts of signification, and the structural consequentiality of sign users' reflexive sensibilities and ideologies about the pragmatic organization of sign use (Silverstein, 1976). This work emphasizes the emergent, contingent character of structure, and as such refuses the objectivist reification of structure that Voloshinov (1972) early identified in the Saussurean paradigm and that Bourdieu (1977) later identified in the Lévi-Straussian one. Finally, Bakhtin (e.g., 1981) has become one ancestral icon of the notion that structure is intrinsically heterogeneous, and that signifying acts by definition occur at border zones joining together multiple, even mutually inconsistent categorial systems.

None of these departures from the thesis of autonomous system can viably abandon the idea of system or structure as such, or some other basic idea of durable relational logic. The central empirical, methodological, and theoretical questions of anthropology remain ones of how to give accounts of sociocultural worlds that document the character of existing relational logics, but neither dissolve those logics into nonrelational determination nor reify them as existing transcendentally unto themselves.

Structuralism: Theoretical and Methodological Assumptions

Most 20th-century humanistic thought notably including semiotics and linguistics as well as the social, behavioral, and cognitive sciences (e.g., sociology, psychology, and anthropology – which the French refer to as *les sciences humaines*) ultimately can be defined and described as belonging to a larger structuralist paradigm originally outlined by Saussure (1966: 16 [1916]), where linguistics was to be part of a larger science called semiology (later to be known as semiotics). Linguistics (as opposed to semiotics) has often been considered to be the better-defined discipline and has even been viewed as the most developed branch within this structuralist paradigm. Within linguistics, the distinction between phonetics versus phonology, the postulation of the phoneme, its various definitions, and the discovery procedures by which it is determined via distinctive features and minimal pairs, etc., have been one of the major cornerstones of structuralism in general and structural linguistics in particular.

Every linguistic theory is the direct result of a specific set of theoretical axioms that is related to how the linguist defines language, defines a linguistic problem, determines the source, kind, and amount of data to be selected and analyzed, chooses a methodology to select and analyze the data, and evaluates, compares, and contrasts the analyses in light of the above. These five criteria basically serve to describe how and what a particular linguist or school of linguistics views as the goals of linguistic research (Tobin, 1990).

Structural linguistics in general and structuralist phonology in particular share a basic definition of language as a hierarchical 'system of interrelated systems which is organized internally and is used by human beings to communicate. **Theoretically,** this definition of language implies a dichotomy between *langue* and *parole*, *langue* being an abstract code composed of signals and meanings and their paradigmatic, or associative, and syntagmatic relations, a complex code that is shared by a community of speakers. *Parole* is the concrete and seemingly chaotic realization of this complex abstract code – exploited by individual speaker – to communicate specific discourse messages in different linguistic and situational contexts. The primary task of the linguist is to postulate the abstract code or system of systems of a language to explain the nonrandom distribution of the linguistic forms of that language in diverse linguistic and situational contexts. **Methodologically,** this definition of language implies a respect for and a reliance on observable empirical data (as opposed to contrived or purely introspective data) culled from discourse and a commitment to deal with the human factor (i.e., the cognitive, perceptual, linguistic and nonlinguistic behavior of human beings) as they are relevant to communication in different linguistic and situational contexts.

Many diverse models of linguistic analysis, both quantitative and qualitative, have been developed to describe, interpret, and explain concrete individual linguistic phenomena (*parole*) according to general, communal, and abstract theoretical principles (*langue*) in various structural guises and under quite different names. The notion of a general structuralist model may be viewed as a theoretical and methodological bridge between the abstract and concrete levels of human linguistic phenomena.

Indeed, one may safely state that a model has been established (a model basically derived from phonology within linguistics) that has been extended throughout the humanities and social or human sciences. This structuralist model for linguistics is illustrated schematically in **Figure 1**.

Structuralism: Theoretical and Methodological Assumptions

Most 20th-century humanistic thought notably including semiotics and linguistics as well as the social, behavioral, and cognitive sciences (e.g., sociology, psychology, and anthropology – which the French refer to as *les sciences humaines*) ultimately can be defined and described as belonging to a larger structuralist paradigm originally outlined by Saussure (1966: 16 [1916]), where linguistics was to be part of a larger science called semiology (later to be known as semiotics). Linguistics (as opposed to semiotics) has often been considered to be the better-defined discipline and has even been viewed as the most developed branch within this structuralist paradigm. Within linguistics, the distinction between phonetics versus phonology, the postulation of the phoneme, its various definitions, and the discovery procedures by which it is determined via distinctive features and minimal pairs, etc., have been one of the major cornerstones of structuralism in general and structural linguistics in particular.

Every linguistic theory is the direct result of a specific set of theoretical axioms that is related to how the linguist defines language, defines a linguistic problem, determines the source, kind, and amount of data to be selected and analyzed, chooses a methodology to select and analyze the data, and evaluates, compares, and contrasts the analyses in light of the above. These five criteria basically serve to describe how and what a particular linguist or school of linguistics views as the goals of linguistic research (Tobin, 1990).

Structural linguistics in general and structuralist phonology in particular share a basic definition of language as a hierarchical 'system of interrelated systems which is organized internally and is used by human beings to communicate. **Theoretically,** this definition of language implies a dichotomy between *langue* and *parole*, *langue* being an abstract code composed of signals and meanings and their paradigmatic, or associative, and syntagmatic relations, a complex code that is shared by a community of speakers. *Parole* is the concrete and seemingly chaotic realization of this complex abstract code – exploited by individual speaker – to communicate specific discourse messages in different linguistic and situational contexts. The primary task of the linguist is to postulate the abstract code or system of systems of a language to explain the nonrandom distribution of the linguistic forms of that language in diverse linguistic and situational contexts. **Methodologically,** this definition of language implies a respect for and a reliance on observable empirical data (as opposed to contrived or purely introspective data) culled from discourse and a commitment to deal with the human factor (i.e., the cognitive, perceptual, linguistic and nonlinguistic behavior of human beings) as they are relevant to communication in different linguistic and situational contexts.

Many diverse models of linguistic analysis, both quantitative and qualitative, have been developed to describe, interpret, and explain concrete individual linguistic phenomena (*parole*) according to general, communal, and abstract theoretical principles (*langue*) in various structural guises and under quite different names. The notion of a general structuralist model may be viewed as a theoretical and methodological bridge between the abstract and concrete levels of human linguistic phenomena.

Indeed, one may safely state that a model has been established (a model basically derived from phonology within linguistics) that has been extended throughout the humanities and social or human sciences. This structuralist model for linguistics is illustrated schematically in Figure 1.

Figure 1 The structuralist paradigm.

Often, this theoretical and methodological model has presupposed an analogy between the model itself and the phenomena it purports to explain. This is not surprising considering the fact that it is the definition chosen for language by the linguist that determines which language phenomena will be selected as being important and relevant for the theory and the analysis. Therefore, the model is predetermined by the theoretical units found in the analyst's definition of language.

Ferdinand de Saussure (1966: 8 [1916]) first maintained that one of the chief tasks of linguistics was to define itself. He further claimed that the objects of study in language are not given in advance, as are the objects of study in other sciences. In short, for linguistics, it is the definition of language espoused by a theory that actually creates the object of study.

The structural model for linguistics that was later extended to other fields and disciplines was originally based on the sound systems of language, namely, the dichotomy between the abstract systems of hypothetical sound units postulated by the linguist and the concrete sounds of language produced and perceived by members of a speech community, which traditionally has been studied under the rubrics of phonology and phonetics, respectively.

More specifically, one may view the dichotomy between phonetics versus phonology in the following way. Phonetics is the description of the way concrete sounds are articulated and perceived – the 'what' and 'how' – of the realized sound systems of languages. Phonology is a postulation of the abstract units of the sound systems of languages (phonemes/distinctive features) as they appear within paradigmatic systems and a description and explanation of their syntagmatic distributions and collocations within and across languages – the 'where' and 'why' of their phonotactic or combinatory distribution. Schematically, one may place phonetics and phonology within the structuralist framework as illustrated in Figure 2.

The theoretical and methodological distinctions between (a possibly autonomous?) phonetics and (a possibly autonomous?) phonology, or the extent to which phonetics may or may not contribute to phonology (or possibly *vice-versa*?) has not always been clearly defined in linguistics and may even be a point of contention between different linguistic approaches.

Structuralist phonology is based on four fundamental theoretical and methodological tenets: (1) The concept of the phoneme composed of distinctive articulatory and acoustic features – sounds that create communicative oppositions – which reflects the abstract level of paradigmatic sound systems in *langue* and underlies the communication factor; (2) The concept of allophones composed of distinctive and secondary or nondistinctive features – sounds that do not create communicative oppositions – which reflects the concrete nonrandom syntagmatic distribution of the variations within a single and specific phoneme and may be related to the human factor; (3) In order to explain why the abstract phonemes of a language may also distribute – like allophones – in a nonrandom manner, we must appeal directly to the human factor in addition to merely classifying the phonemes and their distinctive features that underlie the communication factor; and (4) It is only through the incorporation of the human factor as a means to explain the nonrandom distribution of sounds (beyond the traditional communicative notions of phonemes/allophones and distinctive and secondary features) that a structural analysis can achieve both abstraction (via the postulated units of analysis) and explanatory generality (the ability to explain why these different sound units function and distribute as they do in realized speech in the largest scope possible.

All of the above concepts of system, *langue* versus *parole,* and the distinction between abstract and concrete sound units within paradigmatic systems and their syntagmatic combinations form the foundation of structuralist linguistics and phonology and can be attributed to Ferdinand de Saussure, the 'father' of modern linguistics, who preceded the Prague Circle of linguists who further refined and expanded these concepts in general and in phonology in particular.

Saussurian Phonology

In their usually accepted senses today, the terms 'phonetics' and 'phonology' were basically reversed by

Figure 2 Phonetics versus phonology.

Saussure (1966). Today, what is generally referred to in post-Prague School nomenclature phonetics (i.e., the physiological and acoustic features of sounds and their classification according to those features) was referred to by Saussure as phonology. On the other hand, Saussure defined phonetics in its pre-19th century and 19th century view as an historical science, a study of the diachronic development or evolution of sounds, that is, analyzing speech events and changes over time. Therefore, what Saussure labeled as phonetics (and not phonology) is part of his definition of linguistics as the scientific study of language. Saussure's notion of phonology, however, as consisting of the study of the articulatory mechanism and the various perceptual implications of different speech sounds, all of which do not change, was, therefore, viewed merely as an auxiliary discipline belonging exclusively to the realm of speaking (pre-Prague Circle phonetics). Despite the auxiliary nature of phonology, however, Saussure noted that it served as a necessary tool for dealing with the written forms of language. Linguistic evidence furnished by written forms is valid only when interpreted, thus requiring an understanding of the phonological system of each language, that is, a description of its sounds. Each language, of course, according to Saussure, operates with a fixed number of well-differentiated phonemes.

Saussure laid the foundation for the distinction between phonetics versus phonology (as established by his successors in the Prague School) by establishing the fundamental structuralist concept of system, as well as the dichotomy of the abstract level of *langue* versus the concrete level of *parole*. Furthermore, he laid the groundwork for the teleological, functional, communication orientation adopted by the Prague Circle. Saussure also linked this teleological, functional, communication-oriented approach to the human factor. For Saussure, the description of sounds is directly linked to the articulatory act. The articulatory act is based on two elements that are constant, necessary, and sufficient for the production of sound: expiration and oral articulation (augmented by superimposed vibrations of the larynx or nasal resonances). Thus, Saussurian phonology consisted of the paradigmatic classification of sounds according to their oral articulation and the hierarchical degree of aperture and the organs involved in producing them in a range from total stricture (occlusives) to partial and total opening (vowels) with varied degrees of stricture and opening between these extremes (fricatives, nasals, and liquids). Saussure also recognized the role of the distribution of sounds and the need to study sounds as part of a spoken chain taking the reciprocal relations of sounds into account as part of the study of phonology.

Despite the fact that Saussure predated the sound spectrograph by approximately four decades (and hence the Jakobsonian notion of acoustic distinctive features), his delimitations of sounds within the spoken chain is implicitly based on auditory impressions as well as articulatory movements and mechanisms. If the Saussurian sign was the invariable pairing of signal and meaning, the Saussurian phoneme was the fundamental pairing of the acoustic and the articulatory aspects of the signal. Moreover, for Saussure, oppositions were everything. Therefore, the importance of analyzing phonemes was for the oppositions they created in speech and not only the process through which these oppositions were obtained. Thus, we may view Prague School phonology as a natural extension of Saussurian phonology.

Prague School Phonology

The discipline of phonology was officially presented by three members of the Prague Circle, Roman Jakobson, Sergei Karcevski, and Nikolai Trubetzkoy, at the First International Congress of Linguists at The Hague in 1928. Their primary theses were aimed at distinguishing between the experimental methods of phonetics in observing the individual facts of *parole* and to concentrate on the more general and significant differences and correlations within the structure of the paradigmatic sound systems of *langue*. They outlined the goals of phonology as follows: (1) to establish phonological systems; (2) to account for their significant differences; (3) to find correlations;

(4) to formulate general laws concerning the structure of phonological systems; and (5) to account for historical sound change in terms of a teleological development of a diachronic system.

The Prague Circle concentrated more on the paradigmatic aspects of sound systems, much of the classic research published in the late 1920s and early 1930s in the *Travaux du Cercle linguistique de Prague (TCLP),* although some work was also done on syntagmatic relations related to both possible phonemic combinations and quantitative phenomena (functional load), particularly by Vilém Mathesius, (1929a, 1929b, 1931), who founded of the Prague Circle in 1926. An international conference on phonology was held in Prague in 1930 (whose proceedings were published in *TCLP IV* (1931) and an international committee for phonological research was established which included linguistic circles as well as individual linguists throughout Europe, extending Prague School phonology across international boundaries in France, Holland, Scandinavia, Germany, Austria, and other countries.

The Prague School phonologists differed from Saussure in that they questioned the absolute dichotomy between diachrony and synchrony on the sound level (Fischer-Jørgensen, 1995: 42) and placed the teleological–functional notion of communication at the forefront of phonological analysis, making it the *raison d'être* of phonology. For them, the task of phonology was to discover which differences in sound are related to differences in meaning and to determine how these discriminative elements are related to each other paradigmatically as well as uncover the rules by which they combine syntagmatically to create larger linguistic units such as words and sentences. The underlying force behind phonology as perceived by the Prague Circle is that we speak to be heard and understood, i.e., to communicate, and phonology is the science behind and serves as a reflection of the force of human communication (Jakobson, 1978: 24–25).

As a result of this strong communication basis of Prague School phonology, the notion of the **phoneme** as the minimal psychological and functional phonological unit (signifying distinctiveness or "mere otherness") (Sangster, 1982: 4) became the postulated theoretical abstract sound unit of *langue*. The mutual distinctiveness, or the systematic communicative oppositions between the phonemic units themselves, was then subsequently developed by both Trubetzkoy and Jakobson (as well as by subsequent phonological theorists) into binary and hierarchical articulatory and acoustic distinctive features. Distinctive features allowed for the functional and theoretical oppositions between the phonemic or abstract sound units themselves. These distinctive features – along with the secondary nondistinctive features of allophones – are realized during the speech act of *parole*, but only distinctive features are postulated as part of the abstract code of *langue*.

Distinctive feature theory is perhaps the best-known theoretical construct of Prague School phonology. It, too, like the phoneme and most structuralist concepts, may be viewed as an attempt to postulate abstract categories and constructs that will describe and explain as large and exhaustive amount of concrete linguistic data as possible. Both Trubetzkoy and Jakobson developed sets of 'natural' articulatory and acoustic distinctive features as part of the communication-centered structuralist theory and methodology underlying the work of the Prague Circle.

Trubetzkoy (1931a) postulated three natural classes for vowels (oppositions based on quality, resonance, and prosody) and four for consonants (oppositions of localization, manner of articulation, timbre, and intensity) based on the distinctive feature theory associated with Prague School phonology. For vowels, **the oppositions of quality** included aperture, timbre, rounding, and front versus back; **the oppositions of resonance** included nasalized versus non-nasalized, squeezed versus pure vowels; pharyngeal versus nonpharyngeal sounds; **the oppositions of prosody** included intensity (dynamic – accented versus nonaccented, weak versus strong; and quantity – long versus short, melody (pitch); tone movement and register; as well as oppositions of close contact (Baltaxe, 1978: 72–73). For consonants, **the oppositions of localization** included the different points or places of articulation; **the oppositions of manner of articulation** included voice correlation, correlations based on types of expiration (aspirated/unaspirated, glottalized/nonglottalized, and constriction correlation); **the oppositions of timbre** included palatalized/nonpalatalized, rounded/unrounded, emphatic palatalization/nonemphatic palatalization, emphatic velarization/nonemphatic velarization; retroflex/dental; **the oppositions of intensity** included dynamic (fortis/lenis, squeezed/nonsqueezed (*gedrängt/locker*), strong/weak) and quantity (long/short, geminated/nongeminated) (Baltaxe, 1978: 74–75).

With the advent of the sound spectrograph and subsequent advances made in the field of acoustics, Jakobson (and others) extended the theory of distinctive features to include the acoustic correlates of speech sounds (Jakobson *et al.,* 1952; Jakobson and Halle, 1956). These articulatory and acoustic features have been reduced to a stock of twelve universal binary oppositions which have been used subsequently to analyze the synchronic, diachronic, geographic,

developmental, and clinical phonological systems of individuals and groups representing a wide range of languages and language families. The first nine of these phonological oppositions represent **features of sonority** (similar to the features of quantity and force that are related to the amount and concentration of energy in the acoustic spectrum): vocalic versus nonvocalic; consonantal versus nonconsonantal; compact versus diffuse; tense versus lax; voiced versus voiceless; nasal versus oral; discontinuous (interrupted) versus continuant; strident versus mellow; and checked versus unchecked. The final three features represent **features of tonality** (similar to pitch features and related to the ends of the frequency spectrum): grave versus acute; flat versus plain; and sharp versus plain. Prosodic properties were also studied in detail by the Prague Circle phonologists as vocalic attributes and as features belonging to the larger unit of the syllable or as part of the syllable the mora.

The various feature systems developed by Prague School phonology were used to establish the diverse relationships of opposition that phonemes can have within different paradigmatic systems and syntagmatic contexts. The original distinction postulated for phonemes was one of **correlation** where a certain quality was either **marked** (present) (*merkmal*) or **unmarked** (absent) (*merkmallos*) in members of a number of pairs (such as voicing in the obstruents *p/b, f/v, t/d, s/z*, or vowel length *i/i:, a/a:, u/u:*). The features shared by correlative phonemes constitute an **archiphoneme** (such as the labial stop archiphoneme of *p* and *b* irrespective of the feature of voicing). Noncorrelative oppositions were called **disjunctions** (Jakobson, 1929).

Oppositions can either be **bilateral** or one-dimensional (having two members sharing a single opposition such as the voicing opposition of paired obstruents such as *p/b*), or **multilateral** or multidimensional (having three or more members such as the various places of articulation for a class of sounds sharing a common manner of articulation such as voiceless stops *p/t/k*). Oppositions can either be **isolated** or nonrecurring (such as *r/*) or **proportional** or recurring (such as *p/b, t/d, k/g*).

There are three types of relationships members of an opposition may have: **privative**, **gradual**, or **equipollent**, based on either the presence or absence of a marked/unmarked feature (such as voiced/unvoiced pairs like *p/b*) or the relative degree of the same marked feature (such as vowel height *u-o-(*), or two members are logically equal for the same feature (such as the shared unvoiced property of *p/t, f/k*). In addition, oppositions can be **constant** (both members can occur in the same environment such as voiced/voiceless obstruents in word initial position) or **suspendable** or **neutralized** (such as the neutralization of voicing in German and Russian word-final position where only voiceless obstruents can occur). Where neutralization occurs, it is those features common to both phonemes – the archiphoneme – which appears in its unmarked form which is neutral to the marked feature rather than only signifying its absence.

Another goal of Prague School phonology was the search for general sound laws developed across languages. The most famous of these are the **laws of irreversible solidarity** for the distribution of oppositions across languages, which are believed to be universal: e.g., (1) if a language has back consonants then it has front consonants; (2) if a language has fricatives, then it has homorganic stops; (3) if a language has affricates, then it has homorganic stops and fricatives; and (4) if a language has nasal vowels, then it has corresponding oral vowels. These general sound laws were confirmed by Jakobson's (1941) work in developmental and clinical phonology: (1) children acquire back consonants only after they acquire front consonants; (2) children acquire fricatives only after they acquire homorganic stops, (3) children acquire affricates only after they acquire homorganic stops and fricatives, and (4) children acquire nasal vowels only after they acquire corresponding oral vowels. Jakobson further maintained that the dissolution of aphasic language was the mirror-image of language acquisition: i.e., aphasics lose sounds in the reverse order from which they are acquired.

The Prague Circle viewed diachronic or historical changes in phonology as being related to and even determined by the phonological systems of languages (Jakobson, 1929; 1931a). This represents a teleological or therapeutic approach rather than a mechanistic approach to the establishment and maintenance of the equilibrium of phonemic systems in languages. Some of the processes of phonological change were: phonologization, dephonologization, rephonologization, change in the stock of phoneme combinations, a phoneme may be changed to a phoneme combination, and a phoneme combination may fuse into a single phoneme.

The Prague School phonologists dealt with geographic phonology in two basic ways: Trubetzkoy (1931b) distinguished between three kinds of dialect boundaries: etymological (different pronunciations of the same word within a common vocabulary; phonetic (different pronunciation of the same phoneme within a common phonemic system); and phonological (differences in the phonological system). Jakobson (1931b, 1936), on the other hand, demonstrated that language boundaries and phonological boundaries do not have to coincide, that is, certain phonological

features may be shared by genealogically unrelated languages found in close proximity which are not found in other more distant related languages. Groups of unrelated languages sharing specific phonological features constitute a *Sprachbund,* or a union of languages.

Roman Jakobson, and therefore Prague School phonology, laid the foundation for common laws of solidarity in synchrony, diachrony, developmental phonology, and clinical phonology. Later linguists such as André Martinet, William Diver, and others further sought explanations to explain the connections and the interrelationship between the phylogeny, ontogeny, and the pathology of the development of sound systems in human language in a principled way.

Prague School of Phonology and Beyond

André Martinet took the essentially Prague Circle's notion of the therapeutic view of sound change and further developed it into an explicit and sophisticated functional school of linguistic theory. This functional notion of therapeutic change (the striving for a balance or an equilibrium within the sound system of a language over time as a result of the conflict between the communication and human factors) is rather at odds with the traditional Saussurian synchrony/diachrony dichotomy because, similar to Jakobson and the Prague School, it implies that there is an underlying system in diachrony as well as synchrony in phonology. Martinet (1955) establishes the concept of the 'economy' of sound change in which economy basically refers to the principle of minimal or least effort. While the Prague Circle concentrated on the communication factor, Martinet focused on the human factor.

The introduction of the human factor into phonological analysis (even in the limited guise of Martinet's economy) has several far-reaching theoretical and methodological consequences for the structuralist paradigm: a respect for and reliance on 'real' (as opposed to contrived or totally introspective) language data; the potential importance of frequency counts involving statistics or quantitative methods of linguistic validation; and the need for 'external' (extralinguistic) support as a necessary control for linguistic explanations.

Martinet realized that explanation may not be language internal and that other external factors must also be appealed to. He views these external factors necessary for explanation as being 'historical' in nature rather than appealing directly to the human factor as a primary source for explanation or control. This may be explained by the fact that Martinet only began to incorporate the human factor into his analysis as a function of least effort: i.e., mostly limited to the 'minimax' principle of least effort employed to maintain maximum communication contrasts).

The communication factor adhered to by the Prague School was supplemented by the introduction of the human factor to phonology through the concepts of 'asymmetry' and 'economy of effort' in phonological change by Martinet. He maintained that phonological systems are arranged asymmetrically and changed in such a way that the nonrandom diachronic distribution of sounds reflects the search for equilibrium and harmony within the system as it is affected by the principle of least effort in human behavior. The principle of minimal effort postulated by Martinet implies that speakers strive for a minimal number of phonemes which requires the least amount of effort to be produced and combined in his therapeutic approach to sound change.

William Diver, of Columbia University (where both Jakobson and Martinet taught after World War II), further developed and expanded their ideas in the United States. Diver who basically accepted the Prague Circle's communicative orientation (the concept of the phoneme and the need to establish distinctive features both articulatory and acoustic) as well as Martinet's 'therapeutic' notion of 'economy' and 'asymmetry' (i.e., the inclusion of the human factor in phonological explanation), founded a theory of phonology called Phonology as Human Behavior which combines the communication and the human factors together. Diver (1979, 1995) maintained that there is a constant struggle between our need for maximum communication and our desire for minimal effort, also referred to as 'language synergy' (Tobin, 1990: chap. 3; 1997: 18–23). The communication factor (requiring a large number of maximally distinct linguistic units demanding a great deal of effort) will be in conflict with the human factor (striving for minimal effort), resulting in a synergetic trade-off or compromise between the two. Thus, language may be viewed as a constant struggle and search for maximum communication with minimal effort. This 'minimax' synergetic compromise between the communication and human factors is reflected in the fact that that there is a similar number (20–40) of phonemes of varied proportional degrees of difficulty acquired in a similar order in the languages of the world. Less than 20 phonemes would reduce the communication potential and more than 40 would be difficult to learn, remember, and produce. Therefore, Diver extended Martinet's more limited therapeutic diachronic view of the human factor to that of a means of explaining the nonrandom distribution of phonemes in language in coordination with the teleological needs of communication as originally established by Saussure and the Prague Circle.

Diver and his students also further developed the quantitative analysis of favored and disfavored distributions of phonemes which can be directly related to their degree of relative difficulty and for which additional empirical evidence can be provided by developmental and clinical data (Tobin, 1997) in a way similar to Jakobson (1941). Some of these general sound laws include: (1) Phonemes produced by the apex of the tongue – the most flexible, sensitive, and easiest to control active articulator – are the most numerous and frequent; have the highest functional load; are acquired early; and the process of fronting or apicalization (i.e., nonapical sounds are replaced by apical ones) are among the earliest and most common in first language acquisition and in the clinic; (2) Phonemes produced by the lips and the posterodorsum – which are relatively more difficult to control – are next in number, frequency, and functional load; are acquired both in early and later stages of language development; and the processes of labialization and backing (i.e., nonlabial and nonposterodorsal sounds are replaced by labial and posterodorsal ones) are less frequent, or even idiosyncratic, in first language acquisition and in the clinic; (3) Phonemes produced by the anterodorsum and the glottis – which are the most difficult to control – are the least in number, frequency, and functional load; are acquired relatively late; and the processes of glottalization and palatalization (i.e., nonglottal and nonanterodorsal sounds are replaced by glottal and anterodorsal ones) are among the least frequent, and are considered to be the most idiosyncratic.

The interaction between the human and communication factors is also reflected in the differences of the nonrandom syntagmatic distribution of phonemes in different word positions. Although consonants are more difficult to produce than vowels, the communication distinctions they create are clearer. Therefore, there are more consonants than vowels in all languages, and the most frequent syllable structure in language is CV(C). In word-initial position – where the burden of communication is the highest – there is an almost random distribution of consonants reflecting their different relative degrees of difficulty with a slight favoring of visual–labial phonemes which are perceived both aurally and visually. In word-final position – where the burden of communication is the lowest – there is a highly significant statistical preference for phonemes or clusters of phonemes requiring the least amount of effort to produce: e.g., vowels, or voiceless, apical consonants.

There seems to be a steady progression with regard to the structuralist distinction between phonetics and phonology. Saussure basically provided the notion of system, the abstract level of *langue* versus the concrete level of *parole*, diachrony versus synchrony, and a distinction between 'phonetics' (historical change) versus 'phonology' (the articulatory and acoustic features of sounds. The Prague School subsequently relegated the study of sounds on the concrete level (*parole*) to phonetics and established the new science of phonology to analyze the abstract sound systems of *langue*. This was achieved by introducing the teleological–functional–communication orientation to linguistics. This resulted in the development of modern phonemic analysis and the development of the concept of markedness and distinctive feature theory. Martinet continued this functional approach and began to recognize the role of the human factor as being a crucial part of phonological explanation through the therapeutic view of sound change from the point of view of economy. Diver's approach incorporates the previous work of Saussure, the Prague Circle, and Martinet, but it combines both the human and communication factors together.

Summary and Conclusions

The Prague School's distinction between the study of sounds on the level of *parole* and the investigation of sounds on the level of *langue*, that is, the distinction between phonetics and phonology, was a revolutionary advance in linguistic theory. Thus, the Prague Circle provided a more holistic and systematic approach to linguistic analysis at the expense of the distinction between synchrony and diachrony (at least in the field of phonology). The Prague School introduced the abstract notion of the distinctive phoneme to systematic phonological analysis, thus placing the teleological, functional, communication aspect of the sound system of language at the very forefront of linguistic analysis. This communicative orientation further paved the way for the development of distinctive feature theory as a more abstract, general, and, therefore, scientific method of distinguishing between sounds or phonemes. We may thus view Prague School phonology as the first example of a teleological, functional, communication-oriented structuralist approach to linguistics.

If we view most (if not all) of 20th century linguistics within the generalized theoretical and methodological framework of structuralism, the central role of the Prague Circle becomes clear. The Prague School gave the basic Saussurian tenets of language a theoretical and methodological framework and a direction and purpose. The study of language as an open and flexible system of human communication stratified into mutually interrelated levels and subsystems is the primary legacy of the Prague linguistic circle. Many view the contribution of the Prague Circle in

phonology as its crowning achievement. The Prague School synthesized and formalized the principles of Saussure, thus giving modern linguistics the theoretical and methodological foundation that served as the catalyst for all subsequent structuralist phonological studies within the last 60 years.

Structure and Structuralism: Semiotic Approaches

S Petrilli, University of Bari, Bari, Italy

The Term Structuralism

Structuralism designates a number of different tendencies in different disciplines and spans the entire 20th century. The term 'structuralism' is plurivocal: Several movements and trends have used this name, although they belong to different scientific fields and diverge on the theoretic and methodological levels. The term structuralism may be extended to a number of important schools of thought, including the Saussurean Geneva School (Bally and Sechehaye), the Moscow Linguistic Circle (Nikolaj Trubetzkoy and Roman Jakobson) and the Prague Linguistic School (Vilém Mathesius, Jan Mukařovský, and the same Trubetzkoy and Jakobson).

The Prague Linguistic Circle (founded on October 6, 1926) benefited from the participation of some Russian formalists and developed some of the most influential concepts in structuralism and semiotics. (From 1915 to 1916 Russian formalism gravitated around the Moscow Linguistic Center and the Society for the Study of Poetic Language in Saint Petersburg.) The Prague Circle considered verbal language as being irreducible to a code because language is multifunctional, and its structures are inseparable from dynamic and polysemic processes shaped by both intrinsic laws and external social factors. Natural language flourishes thanks to a great plurality of internal languages connected to differences in the social fabric, as well as to a great complex of special and specialized languages. To study natural language implies investigating the different verbal sign systems – including verbal art, i.e., literature – which are not conceived to be separate from nonverbal sign systems of the culture to which natural language belongs.

Another expression of the structuralist approach is Vladimir Propp's (1928) pioneering analysis of a corpus of Russian folktales. Furthermore, an important contribution to the development of structuralism in the Soviet Union was made by the Moscow-Tartu (Estonia) School between the early 1960s and the end of the 1980s, with its specific focus on semiotics of culture and linguistics. The most renowned representatives of the Moscow-Tartu School include Sebastian K. Shaumyan, Viacheslav V. Ivanov, Jurij M. Lotman, Isaak I. Revzin, Vladimir Toporov, and Boris Uspenskij. The term structuralism may also be extended to both American linguistic-cultural studies (associated with Edward Sapir) and formalistic and behavioristic linguistics (represented by Leonard Bloomfield and Zellig Harris).

We may employ the term structuralism to designate the taxonomic approach to verbal language in linguistics, validly represented by André Martinet's theory of double articulation (into monemes and phonemes) of verbal surface structure, as well as Noam Chomsky's generative grammar, which explains surface structure in terms of transformations in deep structure.

Structuralism also designates certain approaches developed in France such as Claude Lévi-Strauss's anthropology, Roland Barthes's semiology, and Algirdas Julien Greimas's semiotic theory.

Structuralism in general is an approach that explains its objects in terms of their connections and relations of dependency or of reciprocal determination. In this sense, structuralism draws on Ferdinand Saussure's thesis that *langue* is a 'form rather than a substance,' which it extends to semiotics. But a crucial element of differentiation among approaches influenced by Saussurean linguistics is the question of the relationship between synchronic connection and the diachronic processes of formation and transformation, i.e., between structure and history. For example, by contrast with the above-mentioned Geneva School, which opposed structure and process, synchrony and diachrony, and structure and dynamics, the French linguist Emile Benveniste considered the idea of contraposition between structuralism and the historic dimension to be untenable. A similar view was expressed by the Prague Linguistic School and Vladimir Propp. An analogous opposition between structure and dynamics was presented by 'generativist structuralism,' or dynamic structural generative linguistics, and supported by the Russian scholar Sebastian K. Shaumyan (1965).

Louis Hjelmslev, the Danish linguist and semiotician who founded the Linguistic Circle of Copenhagen with Viggo Brøndal in 1931, was deeply influenced by the Saussurean approach to signs and language. However, as much as Saussure was Hjelmslev's starting point for his formalized functional theory of language ('glossematics'), he then developed his own approach in original terms and autonomously. The structure of sign is specified in terms of interdependency between two planes, the **expression** plane and the **content** plane that correspond respectively to the Saussurean *signifiant* and *signifié*. But the Saussurean dichotomy is considered on the basis of a trichotomy figuring – in Hjelmslev's description – **matter** or **purport**, **substance** and **form**. 'Purport,' according to Hjelmslev, is an amorphous continuum "on which boundaries are laid by the formative action of language" (1953: 32–33). Any natural language

articulates the shapeless purport of expression and content in a given way. For instance, the human phonic material of purport is divided into different *figurae* (phonemes) by different languages, just as the continuum of the solar color spectrum is divided into different colors. Variables in the two planes are 'expression substance' and 'content substance,' which are articulated by 'expression form' and 'content form' so as to produce a sign in a specific expression substance (e.g., the acoustic material of a natural language) and in a specific content substance (e.g., the semantic content of a text). The structural semantics of Hjelmslev's glossematics opens up new prospects in semiotics – given its applicability to any sign system, verbal and nonverbal – as well as in the philosophy of language.

Structuralism in the Philosophy of Symbolic Forms

The term structuralism is also employed by the German philosopher Ernst Cassirer, whose most renowned contribution to semiotics is his definition of man as 'the symbolic animal,' instead of as 'the rational animal.' Much contemporary research has demonstrated the aptness of such a definition (see Morris, 1971: 402).

Cassirer's notion of structure is connected with his concept of form and with two concepts evidenced in his book of 1910, *Substanzbegriff und Funktionsbegriff*. The formation of concepts (*Begriffsbildung*) is presented in terms of function and form. In Volume I1, *Die Sprache*, of *Philosophie der symbolischen Formen* (1923), language is presented as form and the study of language is conceived as analysis of the functions generating linguistic form. But he adds another notion in his book of 1923: that of symbol. Thus form is 'symbolic form.'

The Kantian matrix of Cassirer's conception of language offers another perspective with respect to the structuralism of Chomsky's Cartesian linguistics. In his writings, Cassirer developed a perspective that may be characterized in terms of linguistic structuralism (see, in particular, his article of 1946 'Structuralism in modern linguistics'). However, unlike descriptive and taxonomic approaches in structuralism, Cassirer stated the need to evidence the formation process of the structure of language rather than stop at the study of preconstituted forms. Structural linguistics as elaborated in Cassirer's later writings may be defined as a dynamical theory in Shaumyan's sense: that is, a theory that does not identify the synchrony of language with statics, but rather concentrates on the dynamical aspect of the synchrony of language. With such a position Cassirer's theory is not only different from structural linguistics of the taxonomical type, but from Chomsky's theory of language as well.

Structuralism in Biosemiotics

Although structuralism is associated with a widespread movement in the human sciences, other areas of research may also be included in the structuralist enterprise, for instance, the mathematical theory of information, the morphogenetic theory of catastrophes developed by René Thom. Also well known is the biosemiotic doctrine of the 'functional cycle' described by the biologist, he too an Estonian, Jakob von Uexküll: this "pivotal model," this "simple albeit not linear, diagram," which "constitutes a cybernetic theory of modeling so fundamental that the evolution of language cannot be grasped without it" (Sebeok, 1994b: 122).

The '*Funktionskreis*' of Jakob von Uexküll's '*Umweltlhere*' (the term 'Umwelt' was introduced in 1909 to denote the subjective world of an organism) may be considered a structural model for the sign process and a basic structure for global semiosis. In the 'functional cycle,' a 'perceptual cue carrier' (*Merkmal*, i.e., signaling behavior) – produced by the 'objective connecting structure' (*Gegengefüge*, i.e., the *interpretatum*, orobject), and represented in the organism by a 'perceptual mark' (i.e., signaling disposition) – is translated by the interpretant sign into an 'operational cue carrier' (*Wirkmal,* i.e., behavioral disposition). This operational cue carrier triggers a behavior inflicting an 'action-mark' onto the 'connecting structure.' In other words, in the functional cycle, the *interpretandum* (that which must be interpreted) produced by the objective connecting structure effectively becomes an *interpretatum* and (represented in the organism by a signaling disposition) is translated by the interpretant sign into a behavioral disposition which triggers a behavior onto the connecting structure.

Concerning the different models of communication, the functional cycle and the other biological models that describe communication as a self-referential, autopoietic, and semiotically closed system (such as the model proposed by Maturana and Varela), are radically opposed to both the linear (Shannon and Weaver) and the circular (Saussure) paradigms. Uexküll's biosemiosic functional cycle has the feature of autonomous closure and therefore reacts dialogically to its environment only according to its internal needs. Consequently, the autopoietic system theory is not incompatible with the communicative process, but rather, with an oversimplified conception of communication as proposed both by the linear model, which describes communication as a linear

causal process moving from source to destination, as well as by the conversation model governed by the turning around together rule. As Maturana suggests, communication understood as a linear process from source to destination or as a circular process, in which the participants take turns in playing the part of sender and receiver, should be conceived as "pre- or anticommunicative interactions" (1978: 54–55).

The importance of approaches to the structures of sign process, which transcend the field of the human sciences is evident if we consider that semiosis is after all terrestrial biosemiosis. A pivotal concept in Thomas A. Sebeok's research (see 1991, 1994, and 2001) is the identification of semiosis and life. On one hand, semiosis is considered as the criterial feature that distinguishes the animate from the inanimate; on the other, sign processes have not always existed in the course of the development of the universe: sign processes and the animate originated together with the development of life. Identification of semiosis and life invests biosemiotics with a completely different role from that conceived by Umberto Eco (1975) when he refers to 'the inferior threshold of semiotics,' or from its more reductive interpretation as a sector of semiotics which, in his view, is a cultural science. In Sebeok's research, semiotics, as global semiotics, is interpreted and practiced as a life science.

Biosemiotic Structuralism and Dialogism

An important contribution to the understanding of communicative structure is given by dynamic and morphogenetic structuralism inspired by early 20th-century biology and the debate connected with the philososphy of vitalism. Self is implied dialogically in otherness, just as the 'grotesque body' (Bakhtin, 1965) is implied in the body of the other. In fact, dialogue and body are closely interconnected. Dialogism cannot be understood separately from the biosemiotic conception of sign. It is indicative that in 1926, Mikhail Bakhtin, for whom dialogue is the embodied, intercorporeal expression of the involvement of one's body with the body of the other (most adequately expressed by the image of the 'grotesque body'), authored an article entitled 'Contemporary Vitalism' (signed by the biologist I. I. Kanaev). In this article, Bakhtin discussed the biological and philosophical subject. Similar to the biologist Jakob von Uexküll and the development of his research, in Bakhtin too, we find an early interest in biology specifically in relation to the study of signs. Uexküll is named by Bakhtin in this article as one of the representatives of vitalism. In reality, Uexküll did not unconditionally undersign vitalism just as he remained constantly critical of conceptions of the behavioristic and mechanistic type. As he was to state in his book of 1934 (cf. Uexküll, 1967), he was not interested in how the organism-machine works but how the driver works. And Uexküll too was to find an explanation to life in the sign.

In 'Contemporary Vitalism,' Bakhtin's criticism of vitalism – the conception that theorizes a special extramaterial force in living beings as the basis of life processes – is directed against Henry Bergson and specifically against the biologist Hans Driesch. The latter stated the difference between life and non-life and interpreted the organism's homeostasis in terms of radical autonomy from its surrounding environment. On the contrary, Bakhtin, in his description of the interaction between organism and environment, opposes the dualism of life force and physical-chemical processes and maintains that the organism forms a monistic unit with the surrounding world.

In his works of the 1920s, Bakhtin criticizes both the vitalists and the reflexologists, as well as Freudianism and mechanistic materialism (specifically, the mechanistic view of the relation between base and superstructure), on the basis of a dialogic conception of the structure of body and sign and of individual consciousness and social dynamics. In Bakhtin's view, each of these different trends is vitiated by false scientific claims which underestimate the dialogic relation between body and world. This results in either dematerializing the living body or physicalizing it in terms of mechanistic relations. Bakhtin's reflection on sign and its dialogical structure is fundamental to his critique. Reference to the sign's dialogical structure contributes to an understanding of living and psychic structures and processes as well as of historical-cultural structural relations and dynamics, such as that between 'base and superstructure' understood in a Marxist sense, and generally interpreted mechanistically. In fact, another contribution for an adequate understanding of structural processes ensues from replacing both unilinear and conclusive mechanical dialectics with the dialogic model. Uexküll's research develops in the same way. For both Bakhtin and Uexküll the process under examination is a semiosic process. Though Uexküll does not use the dialogic model explicitly, we have seen above how it is central to his 'functional cycle.'

Criteria of Difference among Semiotic Approaches to Structure

First Criterion: Conception of the World to Which Structure Belongs

Semiotic approaches to structure and structuralism may be differentiated on the basis of our understanding

of the world – of the universe – to which structure belongs. Semiotics may either merely describe structures and the worlds they belong to, or may reflect upon the conditions of possibility of what Husserl calls 'the already-made-world,' the already-given, already-done, already-determined world. The second approach in semiotics is necessary to critical analysis of the world's current configuration, with a view to alternative planning. In this case, we may claim that semiotics carries out the overall task of what Edmund Husserl calls 'constitutive phenomenology.' As he shows especially in *Erfahrung und Urteil* [*Experience and judgment*], 1948, the aim of constitutive phenomenology is to clarify the entire complex of operations leading to the constitution of a possible world. To investigate how the world is formed means to deal with the essential form of the world in general and not with the effectively existent world. This means to investigate the modeling structures and processes of the human world not simply in terms of factuality, reality, and history, but also in terms of potential and possibility. Such an investigation is specific in the sense that it deals with a species-specific modality of constructing the world. In fact, unlike other animals, the human animal is characterized by its capacity for constructing infinite possible worlds. With Sebeok we may call the human modeling device of the world 'language.' Such a capacity exists uniquely in the human species, because, unlike all other species, only humans are able to construct not just a single world but innumerable real or imaginary, concrete or fantastic ones (cf. Sebeok, 1991a).

Second Criterion: Use of the Notion of 'Code'

Use of the notion of 'code' is symptomatic of differences in semiotic approaches to structure and structuralism. As anticipated, such difference depends on whether a given approach limits itself to merely describing 'the already-made-world' or, instead, reflects upon conditions of possibility. Paul J. Thibault (in the entry 'Code,' Bouissac, 1998: 125) illustrates how this ambivalent notion in semiotics can be used to denote (1) a set of shared rules of interpretation and (2) a 'meaning-making' potential. The first view coincides with a model of communication understood as transmission of information encoded by the sender and decoded by the receiver on the basis of a common code which is neutral, immune to interpretation, and sufficient for communication to come off successfully, what Rossi-Landi (1998 [1961]) ironically calls 'postal package model.' This model, says the entry 'Code,' derives from Saussure's dichotomy between code (*langue*) and individual use (*parole*). It also derives from the first generation of research in information theory (Shannon and Weaver, 1949) and cybernetics (Norbert Wiener, Ross Ashby) and was influential in the development of semiotics in the 1960s and 1970s. Eco (1976) referred to this conception of communication when he distinguished mechanistic communication systems from systems of signification.

The second model of code in semiotics maintains that code and medium have "a significant meaning-making potential" (Bouissac, 1998: 126). This implies that

> Code, in this view, is a semiotic resource – a meaning potential – that enables certain kinds of meanings to be made (in language, in the ways we dress, in our eating rituals, in the visual media, and so on) while others are not, or at least in that code. This view differs from the previous one in two important ways. First the internal-design features of the code – its grammar – have a significant potential for constructing meanings. . . . Second, there is no dichotomy between code and behavior or use (126).

According to the author of the entry 'Code,' representatives of this second view of code in semiotics are Bronislaw Malinowski (cf. Ogden and Richards, 1923), Gregory Bateson (1951), with his model of codification as a multilevel and hierarchical system of contextualizing relations, and Michael Halliday (1984).

The overcoming of the semiotic conceptions of structure connected to the notion of code as a mechanistic communication system, and the transition from communication semiotics to interpretation semiotics are inseparable from the 'rediscovery' of Peirce's semiotics in the 1970s, as results from Eco's book of 1976: indeed, all this is an expression of the confluence between Saussurean 'semiology' and Peircean 'semiotics' (a tendency to "ecumenicalism in semiotics," as says Sebeok, 1979: 61–83). Eco's research may be cited to demonstrate the fortune of the notion of code in the development of semiotics from the 1970s, as well as to evidence Peirce's influence on transformation. Eco's concern with Peirce's semiotics can be traced in his studies to the triadic relation between sign (representamen), interpretant and object, sign production, the mechanism of abduction, interpretation of the text and its relation with the reader, reformulation of the notion of code and of dictionary semantics in terms of encyclopedia, and of Peirce's notion of 'infinite semiosic process.'

In *The limits of interpretation* (1990) and in *Interpretation and overinterpretation* (1992), Eco revisits the question of openness (cf. 1962, 1990, 1992), in terms of 'unlimited semiosis.' In his recent book of 1997, Eco turns his attention to the question of the

Peircean notions of 'dynamical object' and 'ground.' But gradual distancing from Saussurean semiology, i.e., **ontological** structuralism (cf. his critical book *The absent structure*, 1968) – the idea of a binary relation between signifier and signified and between code and message – led Eco to assert the following as early as 1976 (in his paper on Peirce's notion of interpretant delivered at the Peirce Symposium on Semiotics and the Arts at Johns Hopkins University in Baltimore): "I want to make explicitly clear that my present approach has to be labeled *Peircist*" (quoted from Sebeok, 'Foreword,' in Capozzi, 1997: xiii).

According to Eco (1976), a code governs information transition from a source to a destination, but a code alone does not guarantee signification, since a connection cannot be established between (a) a set of signals ruled by internal restrictions of combination, and (c) a set of possible behavioral responses by the destination, without (b) any notion from a set of notions about the state of the world, which can become communicative contents. Systems (a), (b), and (c) are called 's-codes.' An S-code is "a system (i) in which every value is established by positions and differences and (ii) which appears only when different phenomena are mutually compared with reference to the same system of relations" (Eco, 1976: 38). As Proni says in his article (Posner *et al., Semiotik / semiotics* [hereafter *SS*], 2: 2314), Eco synthesizes "the Hjelmslevian and structuralist approach with Peirce's theory of interpretation" (*SS*, 2: 2314). In the words of the entry 'Eco' in *Encyclopedia of Semiotics*:

> In keeping with his trademark hybrid blend of Hjelmslevian and Peircean categories, Eco reduces the two continua of the expression and content planes of Hjelmslev to one continuum; the matter through which semiosis takes place. Semiotic interpretation involves the application of Peircean concepts to define the segmented portions of the continuum serving as sign vehicles for content segments (Bouissac, 1998: 222).

Consequently, another criterion of difference between the semiotic approaches to structure may be their belonging to 'semiotics of code or to 'semiotics of interpretation.

Third Criterion: Difference between 'Code Semiotics' and 'Interpretation Semiotics'

The expression 'code semiotics' alludes to a general model of sign according to which messages are formulated and exchanged on the basis of a code that is defined and fixed antecedently to the actual use of signs. And given that the code is based on a two-way correspondence between *signifiant* (or *signifier)* and *signifié* (or *significatum)*, it calls merely for decodification without involving the risks of interpretation. Code semiotics ensues from a limited interpretation of Saussure's research and reformulates the information, or mathematical theory of communication in terms of the Saussurean sender/receiver model (see Shannon and Weaver, 1949, and Jakobson's model of communication). We know that the Saussurean sign model is grounded in a series of dichotomous pairs comprising the notions of *langue* and *parole*, *signifiant* and *signifié*, diachrony and synchrony, and the syntagmatic and paradigmatic axes of a sentence. This dichotomous view of communication favors the connection between the Saussurean model and the mathematical theory of communication, and therefore, reformulation of this model in such terms as **code** and **message**, **transmitter** and **receiver**. This explains why semiotics of Saussurean derivation has been described as 'decodification semiotics' (Rossi-Landi, 2003 [1968]), or 'code and message semiotics' (cf. Bonfantini, 2004 [1984]).

This model appears ever more inadequate in the light of Peirce's 'interpretation semiotics' (but also Bakhtin's philosophy of language: see Augusto Ponzio, 'Semiotics between Peirce and Bakhtin, in Ponzio, 1990: 251–273), and of social-cultural transformations that tend towards new signifying practices that are intolerant of the processes of polarization between code and message and, in fact, weaken the code's hegemony over the multivoicedness and multiavailability of sign. Moreover, meaning in semiosic processes is inseparable from the work of translation carried out in the process of interpretation, to the point that, with Peirce, we may state that signs do not exist without another sign acting as interpretant.

Structure as '*a priori*' and Structure as 'Interpretive Process' in Semiosis

We may distinguish between two conceptions of structure: in the first case, structure is given *a priori* with respect to semiosis, to sign process or sign relation, which is reduced to codification and decodification; in the second case, structure (for example, in Peirce the triadic structure of sign, or of argument) is inseparable from the effective process of semiosis, that is, from interpretation which is what semiosis consists of.

As Sebeok observes in his article in *Semiotik / semiotics*, 'The evolution of semiosis', the Peircean description (Peirce, 1931–1966, *Collected Papers of Charles Sanders Peirce* [hereafter *CP*], 5: 473) of semiosis or "action of a sign," conceived as an irreducibly triadic process or relation (sign, object, and

interpretant), focuses particularly upon the way the interpretant is produced. Therefore it concerns "what is involved in understanding or teleonomic (that is, goal-directed) interpretation of the sign" (*SS*, 1: 436). In terms of Roland Posner's description mentioned above (*SS*: 1), semiosis calls for the action of something 'purposive.' *Signans* and *signatum*, or, in Saussurean terms, *signifiant* and *signifié*, are part of an irreducibly triadic sign structure.

Peirce himself underlines that the term 'representation' is inadequate to indicate the general reality of the sign. He avers that signs and sign processes are far better described in terms of 'mediation' (*CP* 4: 3), which presupposes the work of interpretation. The sign, more than 'represent' the object to the interpretant, mediates between the object and the interpretant. In other words, the semiosic function is best described in terms of 'mediation' (interpretation) rather than 'representation' (cf. *CP* 4: 3). While the expression *aliquid stat pro aliquo*, that is, 'something that stands for something else, describes the sign relation in dyadic terms, Peirce's definition evidences the irreducibly triadic structure of the sign relationship and places the condition for theorizing the movement of *renvoi* and transferral that characterizes it. Sebeok emphasizes this aspect of Peirce's analysis of sign structures and relations when he says:

> Peirce's definition embodies the core concept of *renvoi,* or transfer, Jakobson's compressed coinage (*Coup d'œil sur le développement de la sémiotique* [1975]) for the celebrated antique formulation, *aliquid stat pro aliquo*, but it contains one very important further feature. Peirce asserts not only that *x* is a sign of *y*, but that 'somebody' – what he called 'a *Quasi-interpreter*' (*CP* 4: 551) – takes *x* to be a sign of *y* (Sebeok, 1979: viii).

Not only is a sign a sign of something else, but 'somebody' a '*Quasi-interpreter*' (*CP* 4: 551) assumes something as a sign of something else. Peirce further analyzes the implications of this description when he says: "It is of the nature of a sign, and in particular of a sign which is rendered significant by a character which lies in the fact that it will be interpreted as a sign. Of course, nothing is a sign unless it is interpreted as a sign" (*CP* 2: 308). And again: "A sign is only a sign *in actu* by virtue of its receiving an interpretation, that is, by virtue of its determining another sign of the same object" (*CP* 5: 569). Semiosis considered from the point of view of the interpretant and, therefore, of sign-interpreting activity, or the process of inferring from signs, may be described in terms of **interpretation**. Peirce specifies that all "signs require at least two *Quasi-minds;* a *Quasi-utterer* and a *Quasi-interpreter*" (*CP* 4: 551). The activity of engendering the sign and that of interpreting it, that is, 'utterance' and 'interpretation,' are essentially interconnected by a relation of continuity and as such describe two faces of the same thought process – nor does the latter necessarily pass through the human brain. The Peircean sign model is today gaining wide consensus in both semiotics and the philosophy of language. It is gradually supplanting the model of semiosis understood mechanistically as codification and decodification – which because of the spread of Saussurean structuralism has extended its influence from linguistics (and semiology) to other human sciences.

Despite consensus around the Peircean sign model, the mechanistic model continues to be applied in semiotic and linguistic studies:

> Nevertheless, the mechanistic model retains a powerful hold on theories of human communication .... For Noam Chomsky, a generative grammar is a system of rules for relating signals to their semantic representations. Chomsky claimed that this pairing of signal and semantic representation corresponds to the idealized competence of the speaker-hearer. This competence specifies the underlying mental mechanism that makes this pairing process possible. This model continues to exert influence (Bouissac, 1998: 126).

Binarism and Triadism in Structuralist Semiotic Approaches

The difference in the structuralist conception between decodification semiotics and interpretation semiotics transcends the opposition between binarism and triadism. Saussurean/Hjelmslevian/Greimasian semioticians, on the one hand, and Peircean semioticians, on the other, do not represent two factions siding either with binarism or with triadism. The heart of the matter does not at all lie in the opposition between binarism and triadism. Instead, the pivotal issue is the opposition between semiotic models of structures that tend to oversimplify things with respect to the complex process of semiosis and semiotic models of structures, which would seem to do more justice to the various aspects and factors of the semiosic process. This is not merely achieved on the basis of an empty triadic form, but rather thanks to the specific contents, the specific categories forming the approach, the typology of sign it proposes, and the dynamic model of structure it offers on describing its objects. The sign model proposed by interpretation semiotics is constructed on the basis of such categories as Peirce's tripartite division of interpretants into 'immediate interpretant.' 'dynamical interpretant,' and 'final interpretant,' his subdivision of the object into 'immediate object' and 'dynamical object,' and his main triadic division of signs into 'symbol,'

'index,' and 'icon,' etc. All the same, it is not triadism that is essential, but the fact that Peirce places the sign in the dynamic context of semiosis (developing the concept of 'infinite semiosis'), and the dialogic relation to the interpretant. Considering such aspects, independently from the question of binarism or triadism, we may associate Peirce with Bakhtin and the former's fundamental notion of 'interpretation' with the latter's fundamental notion of 'answering comprehension.' The merit does not go to the triadic formula. Proof for this is offered by Hegelian dialectics in which triadism, abstracted as it is from the constitutive dialogism of sign life, gives rise to metaphysical, abstract, and monological dialectics. It is odd that in the entry 'Binarism' in *Encyclopedia of semiotics*, the author should propose Hegelian philosophy as a means of overcoming the theory of binary opposition in Lévi-Strauss's structuralism (cf. Bouissac, 1998: 81). Bakhtin, in his 1970–1971 notebooks (Bakhtin, 1979), gives a good explanation of how Hegelian monological dialectics is formed, showing how it is constructed artificially proceeding from a vital and dialogic sign context. In fact, the process consists in taking out the voices (division of voices) from dialogue, eliminating any (personal/emotional) intonations, and thus transforming live words into abstract concepts and judgments, so that dialectics is achieved in the form of a single abstract consciousness. Peirce himself also took a stand against the systemic skeleton of Hegelian analysis, against dialectics understood as a kind of hypochondriac search for an end, a search that is oriented unilaterally instead of being open and contradictory (on the relation between dialogue and dialectics in Peirce and Bakhtin, see Bonfantini *et al.*, 2000).

Monologism and Polylogism in Semiotic Approaches to Structure and Structuralism

The alternative in semiotic approaches to structure and structuralism is not between binarism and triadism, but between 'monologism' and 'polylogism.' Of course, we know that the Saussurean sign model is grounded in a series of dichotomous pairs comprising the notions of *langue* and *parole*, *signifiant* and *signifié*, diachrony and synchrony, and syntagmatic and paradigmatic axes of language. And certainly, this dichotomous view favors the connection between the Saussurean model and the mathematical theory of communication, and therefore, reformulation of this model in such terms as **code** and **message**, **transmitter** and **receiver**.

Signal Structure and Sign Structure

This explains why semiotics of Saussurean derivation has been described as 'decodification semiotics.' Despite their reductive character in relation to signifying and interpreting processes, such concepts as these were thought for quite some time to adequately describe all types of sign processes. They were employed to describe not only simple sign processes of the **signal** type relative to information transmission, but also sign processes of the complex type, the **sign**, in the strict sense, relative to human communication in its universality and in its different aspects. Signals are signs with the least semiosic consistency, that is, at the lowest level of semioticity. Signals presuppose a code, a system of rules with respect to which the relation between interpreted and interpretant is predetermined. But the signal is a constitutive component of signs in general more than just one type of sign. From this point of view, rather than use the term 'signal,' which suggests something separate from sign, 'signality' is more appropriate to indicate the lowest level of semioticity or **signhood**. For example, as much as the verbal sign is characterized by multivoicedness, it too contains a margin of signality. In other words, verbal signs are signals as well under certain aspects, so from a certain point of view, signs too present a univocal relation between interpreted and interpretant. With signality, signs are at the lowest level of interpretation, that of identification or recognition.

As we have proposed in earlier writings, the interpretant sign relative to the signal or signality may be called 'interpretant of identification.' In the case of verbal signs, for example, the interpretant of identification (a) permits recognition of phonemic or graphic contour, (b) identifies semantic content ('immediate interpretant' in Peirce's terminology; 'meaning' versus 'theme' in Bakhtin-Voloshinov's terminology), and, last, (c) identifies morphological and syntactic configuration. The relation of the identification interpretant to the interpreted is univocal and predetermined by a code, similarly to the relation between interpretant and interpreted in signals. But the signal component of the verbal sign does not characterize it structurally as a sign. For this reason, a structural description of the verbal sign limited to such aspects does not account for its specificity as a sign. In other words, like all other signs, except for signals, in *strictu sensu*, the verbal sign too is made of signality, but its structure is not reducible to the latter (cf. Ponzio, 1990 and 1993).

The limit of structuralism proposed by the semiology of Saussurean matrix is not determined by binarism. On the contrary, the limit is that binarism finds expression in the concept of equal exchange between

signifier and signified, in the reduction of complex sign life to the dichotomy between code and message, and consequently in the reduction of signhood to signality. Interpretation semiotics evidences the inadequacy of the sign model subtending decodification semiotics. No doubt 'rediscovery' of interpretation semiotics has been favored by new socio-cultural orientations arising from signifying practices that are intolerant of polarization between code and message, *langue* and *parole*, language system and individual speech. Such signifying practices flourish simultaneously to the weakening of centripetal forces in linguistic life and socio-cultural life generally, which privilege the unitary structure of code over the effective polylogism, plurilingualism, multiaccentuativity, and pluriavailability of signs.

Structuralism in the Generative-Transformational Approach

Similarly to the Saussurean model, the **Chomskyan** model is also dichotomous (competence/performance, surface/deep structure, innate rules/experience), but in this case too the limit of Chomskyan structuralism does not rest at all in the opposition between binarism and triadism. Chomsky's structuralist theory of transformational grammar studies rules of transformation from 'deep structures' to 'surface structures.' As demonstrated by Ponzio (cf. 1992 and 2004, this distinction (introduced in Chomsky, 1965), as well as the previous between 'nuclear' and 'non-nuclear sentences' (Chomsky, 1957), is connected with a very questionable conception of language and knowledge and with an equally questionable method of analysis.

Apart from previous criticism, his limits in linguistics inevitably emerge in the light of a Peircean and Morrisian approach to the study of signs. Chomsky sees no alternative to vulgar linguistic behaviorism (such as Burrhus Skinner's), other than appealing to the rationalistic philosophy of the 17th century, and taking sides with mentalism and innatism. That the Chomskyan conception of language should remain tied to the classical alternatives between consciousness and experience, and rationalism and empiricism, is not devoid of negative consequences for a theory of language, even with respect to such a specialized branch as is syntax. From this point of view, Chomsky's approach is alien to Kantian criticism as much as to the conceptions of Edmund Husserl, Peirce, Ernst Cassirer, Maurice Merleau-Ponty, Charles Morris, etc. Unlike Chomsky's dichotomy between linguistic competence and experience, in modern conceptions after Kant, experience is described as a series of interpretive operations.

These include inferential processes of the 'abductive' type (Peirce) through which the subject completes, organizes, and associates data, which are always more or less fragmentary, partial, and discrete. Experience coincides with these operations, as such, it is innovative and qualitatively superior by comparison with the limited nature of eventual input. After all, experience coincides with competence. What Chomsky (1986) baptized 'Plato's problem' ('how does complete competence derive from limited linguistic experience?') is a consequence of the false dichotomy between competence and experience and of the ensuing conception of experience as a passive state of the subject.

Morris's concept of syntactics as well as the notion of syntax which belongs to it are connected with semantics and pragmatics. Instead, Chomsky's syntax – as well as his phonology and semantics (morphology) – belongs to syntactics equated with syntax, as in Rudolf Carnap, and separated from semantics and pragmatics. As specified in the article 'Syntactics,' by Posner (*SS*, 1: 14ff), and in accord with Charles Morris's conception of the branches of semiotics (syntactics, semantics, and pragmatics), in linguistics, phonology, syntax (in the strict sense), and the morphology of natural language all fall under **syntactics**. With regard to the difference in this sense between syntactics and syntax, Posner observes:

> In many contexts, the Carnapian identification of syntactics with syntax (cf. Carnap 1934 and 1939) is highly misleading. Only in sign systems which do not require a distinction between morphology and syntax is it unproblematic to equate syntactics with syntax. This is the case in sign systems such as numerals and in most of formal languages constructed in logic so far (Posner *et al.*, 1997: Vol. 1, 21).

Posner distinguishes between three aspects of syntactics, which are all present in Morris (1971: 13ff, 23ff, 28f, respectively): syntactics, the study of formal aspects of signs; syntactics, the study of relations of signs; syntactics, the study of how signs of various classes are combined to form complex signs (cf. *SS*, 1: 14). A branch of syntactics, understood as the study of combination rules to form complex signs, is the study of combination rules in a sign system called 'string code.' An example of syntactics, says Posner, is Chomsky's transformational grammar which studies rules of transformation from 'deep structures' to 'surface structures' (cf. *SS*, 1: 30–37).

As demonstrated by Ponzio, Chomsky confuses levels of analysis and mistakes the description of the objects of analysis for the construction of the models of analysis. In this sense, unlike Rossi-Landi's (1998 [1961]) 'methodics of common speech' (see Ponzio,

1990) or Shaumyan's (1965) bigradual theory of generative grammar, Chomsky's structuralism is a unigradual structural theory which fails to distinguish between the **genotypical** (ideal) level and the **phenotypical** (empirical) level of structures. This is a serious limit in Chomskyan generative structuralism.

Chomsky's error is no different from that made by Oxonian analytical philosophy. Representatives of analytical philosophy claimed to describe ordinary, daily, or colloquial language in general. In reality, however, they described the characteristics of a given natural language. Confusion between two levels, the general and abstract level of language, on the one hand, and the particular and concrete level of a given language at a certain moment in its historical development, on the other, is recurrent – and not only in the Oxonian conception or in more recent language analyses inspired by the latter. Chomskyan generative grammar also mistakes the specific characteristics of a given language – yet again English – for the universal structures of human language. The untranslatability of sentences used by Chomsky as examples of his analyses is symptomatic of the problem we are signaling. The structuralistic transformational model proposed by Chomsky confuses elements which in reality belong to two different degrees of abstraction, ideal language, and natural language.

The Role of Interpretation in the Structural Dimensions of Semiosis

Furthermore, Chomskyan theory of linguistic structures denies the interpretive character of the syntactic component of linguistic competence and limits interpretation to phonological and semantic components alone. Consequently, Chomsky separates 'to **generate**' (which concerns relationships between 'deep structures' and 'surface structures') and 'to **interpret.**' He privileges syntax and considers it as an unfounded fundamental, an *a priori* conceived in terms of innatism, freeing it from interpretation and exempting it from the dialogic relation between interpreted and interpretant (see Ponzio, 2004: 42–44).

Thus, Chomskyan grammar with its methodologic suppositions and dualism between competence and experience and between deep structures and surface structures, would not seem to offer a suitable example of syntactics as understood by Posner and in accord with Morris's approach to semiotics.

Ponzio in various writings (1990, 2004) has proposed, as a branch of syntactics that studies combination rules applied to verbal form complexes, a 'structural interpretive linguistic theory' able to 'generate' (in Chomsky's sense) an utterance in terms of its relation to another utterance that interprets it, that acts as its interpretant. In fact, all utterances are engendered, that is, produced, identified, and characterized by their interpretants. According to this approach, the interpretant of a 'sentence' (the dead cell of a linguistic system) or, as we prefer, 'utterance' (the live cell of discourse) is not a deep structure grounded in underlying elementary sequences, but another verbal sign. An interpretant identifying an utterance or any verbal sign whatever is simply 'unexpressed' until the conditions are realized for its expression, its explicitation. We have introduced the expression 'identification interpretant' (cf. Ponzio, 1990) for this type of interpretant which (a) identifies the verbal sign in its phonemic or graphic features, (b) identifies the verbal sign in its semantic content, and (c) identifies the morphological and syntactic physiognomy of the verbal sign.

Given that the three structural dimensions of semiosis (syntactical, semantical, and pragmatical) are inseparable, the interpretant engendered by an utterance or any verbal sign whatever is not only an identification interpretant. It is also an 'answering comprehension interpretant,' which has a special focus on the pragmatical dimension of signs. Without the interpretant of answering comprehension, it is difficult, if not impossible, to recognize the sign at the level of phonemic or graphemic configuration, or morphological and syntactic structure, as well as semantic content. Just as Charles Morris highlighted the presence of syntactics in all aspects of signs, in the same way we must underline that meaning (i.e., the relation between interpreted and interpretant) is also present at the level of identification of the units composing words, phrases, utterances, and texts.

A Pioneer Bigradual Approach to the Genotypic Structures of Language

As stated, a fundamental limit evidenced by Sebastian Shaumyan in Chomsky's transformational model is that it confuses elements which in fact belong to two different degrees of abstraction, ideal language and natural language: Chomsky's model cannot be applied to a natural language different from that elected for his description. This led Shaumyan to contrast his own bigradual theory of generative grammar to Chomsky's unigradual theory: differently from Chomsky, Shaumyan distinguished between two levels of abstraction, genotypic language and phenotypic language.

With his pioneer book of 1961, *Significato, comunicazione e parlare commune* (new edition, 1998), which also anticipates Shaumyan's book *Strukturnaja linguistica* ('Structural linguistics,' 1965), Rossi-Landi much like Shaumyan also proposed a bigradual

approach to language. Rossi-Landi introduced the concept of 'common speech' to indicate operations carried out through speech, considered essential for successful communication among human beings, independently from the obvious complications arising in concrete reality. The assumption subtending this concept is that there exist basic similarities in the biological and social structure of all human communities, beyond all possible historical and geographical differences.

Common speech explains and justifies linguistic difference, variety, and multiplicity in terms of variety in expedients, solutions, and resources offered by each single language to satisfy the social needs of expression and communication common to all languages. And, of course, nothing is ever complete and definitive given that language is continuously developing and transforming. By contrast with those trends that conduct the multiplicity of languages to an *Ursprache,* or to the universal linguistic structures of logos or to a common biological structure, the notion of common speech does not neglect or underestimate what George Steiner (1975) indicated as 'the enigma of Babel,' which alludes to diversity and multiplicity among languages. Common speech as proposed by Rossi-Landi does not imply mythical unity at the origin of all languages, and even less unity of the human species by natural law. The notion of common speech proposes a model; in other words, it is a theoretical construction and not a *direct* description of real processes, though it refers to real processes.

By contrast with the concept of ordinary language developed by the analytical philosophers and the notions of competence and generative grammar proposed by Chomsky, common speech is a model with interpretive functions, a hypothesis to apply to different languages. In other words, rather than **describe** linguistic usage, common speech (or 'speaking') aims to develop a general model able to **explain** linguistic usage, and as such may be applied to all languages. In this sense, that which subtends linguistic usage is not mentalistic or ontologically pre-existent to natural languages in any other way: Rossi-Landi's model is the result of interpretive hypotheses and proposes a conceptual apparatus for the understanding of real linguistic phenomena. With his 'methodics of common speech,' Rossi-Landi's approach to the structural features of languages explains concrete linguistic usage in a given natural language (phenotypic level) in terms of his common speech hypothesis (genotypic level), whose validity increases the more it may be extended to different languages. Rossi-Landi himself guided us toward such an interpretation with the following statement from the foreword to the first edition of *Significato, comunicazione e parlare comune*:

> ... both the claim to a science of sign behavior of the biopsychological or sociological type and competition with the analytical and historical work carried out by glottologists on the facts of the various languages are excluded. It does not follow from this that what I wish to offer is some sort of theory or general doctrine, of the cognitive speculative type, as regards the phenomena under examination. Rather, I merely want to offer a structural background and make an attempt at clarification. To study the a priori in language does not mean to adopt a deductive aprioristic method. (Rossi-Landi, 1998 [1961]: 9)

This is the hypothetical-deductive method or more properly the abductive method, to evoke the Peircean concept of 'abduction,' which explains a given event on the basis of hypotheses concerning the general conditions that make that event possible.

'Critical Structuralism'

In a semiotic perspective we can connote structuralism as 'critical structuralism' insofar as it is concerned with the general conditions that make meaning and communication possible. 'Possible' is understood here in Immanuel Kant's sense and refers to the *a priori* in language, that is, the conditions that make facts possible, rather than the investigation of these facts. This point of view is emblematic of Rossi-Landi's research on the common structures of different natural languages, which he calls common speech (as we have seen). In fact, for Rossi-Landi, 'common speech' has a methodic function. In the light of this interpretation, the study of language is the search for a general methodology of language and of human speaking in its signifying capacity (cf. Rossi-Landi, 1998 [1961]: 158 ff:). Common speech evidences how language functions, signaling those operations that are inevitably performed when we speak. In relation to this aspect, Rossi-Landi's investigation is inspired by Kantian transcendental logic, which he reformulated. But, at the same time, common speech theory goes beyond Kant because it insists on what Kant left aside, that is, the transcendental character of language. Significantly, Rossi-Landi's rereading of Kant was filtered by Ernst Cassirer (in particular his 'Structuralism in modern linguistics'), the 'Kantian Peirce,' and the British analysts. The *a priori* lies in language. Common speech should not be reduced to "expressed linguistic" results, but rather concerns the "internal and hidden structure" of language (*ibid.*: 165).

This concept implicitly refers to the concept of '*innere Sprachform*,' borrowed by Cassirer from

Karl Wilhem von Humboldt and connected with the view of language as *energheia* rather than as product, *ergon*. We could maintain that Rossi-Landi takes an *ante litteram* critical stand against Chomsky's 'Cartesian linguistics' (the title of the latter's 1966 essay in which he attempts to assimilate Humboldt and Kant into his own perspective). Given that Chomsky's conception of language is not free of the classical alternatives 'consciousness/experience' or 'rationalism/empiricism,' his approach is alien to both Kantian critique and its surpassing by abstract rationalism and abstract empiricism.

We must remember that Peirce's semiotics is also connected with Kantian philosophy. In fact, he proposed a 'New list of categories' (*CP* 1:545–559), reinterpreting the *a priori* and the transcendental in linguistic and semiotic terms. Peirce's semiotics is explicitly anti-Cartesian and refuses the rationalism-empiricism dichotomy as unfruitful and abstract (cf. his essays of 1868, 'Questions concerning certain faculties of man' and 'Some consequences of four incapacities,' in *CP* 5:215–263, *CP* 5:264–317, respectively). For Rossi-Landi both the generic opposition of idealism to empiricism and of logico-linguistic inquiry to historicism in the study of the structural processes of signifying is inconsistent and arbitrary. He underlined the importance of Giambattista Vico's historicism for a critique of the Cartesian model of knowledge, which insofar as it was based on evidence and deduction, could not be applied to the historical or 'human' sciences.

Semiotic Structuralism in the Marxist Approach

Another important semiotic structuralist approach that should be mentioned in this overview is Karl Marx's 'protostructuralist' analysis of capitalist economic relations. We shall not refer to French Marxist structuralism (Louis Althusser, Lucien Godelier – the Marxist structuralism of Lucien Sebag, follower of Lévi-Strauss, is a 'discours à part'), but directly to Marx given that his approach is typically semiotic (see Ponzio, 1990: 174–188), even if we must connote it as 'criptosemiotic.'

The study of communication is pivotal in the Marxian critique of political economy. In fact, Marx analyzes commodities as messages and concentrates on explaining the "language of commodities" and the "commodity's arcanum" (see Marx, 1976, 1). As a result of this approach, his critique of political economy overcomes the fetishistic view of things according to which the relation among commodities appears as a natural relation among things and not for what it really is, that is, a specific type of relation among people. As such, Marxian critique is effectively a semiotic analysis which studies the structure of goods as messages not only at the level of exchange but also of production.

A commodity is a commodity not when a product is produced and consumed in its use-value but when it is produced and consumed as an exchange-value, that is, as a message. All this makes economics a sector of semiotics (see Rossi-Landi, 1975).

The structure of the market emerges as a structure of human relations, precisely, the human relations of social production. From this point of view, the Marxian approach to structure is exemplary for semiotics. It indicates that what Marx achieved in his analysis of commodities and capital we must achieve in anthroposemiotics: structures of relations among human individuals must be identified in the place of mere relations among things and individuals reduced to things.

Vice versa, the semiotic approach permits an appropriate use of the notions of structure and superstructure in a Marxist framework. In fact, recurrent difficulties in the study of the relations between structure and superstructure derive from the lack of a mediating element. This mediating element is provided by the totality of sign systems, verbal and nonverbal, operative in all human communities. The pieces in the game are not two, but three: to the modes of production and to the ideological elaboration of the superstructure must be added **sign systems**.

Intersemiotic Translation of Semiotic Approaches to Socio-Cultural Structures

In a semiotic perspective, the structures of nonverbal communication, i.e., the circulation of commodities and the structures of verbal communication, i.e., the circulation of messages, appear as different structures of the same social process, i.e., the communication process. "Man communicates with his whole social organization," writes Rossi-Landi (2003 [1968], Eng. trans.: 67).

This means that all cultural phenomena may be viewed as communicative phenomena based on sign structures and systems, and that human nonverbal communication must be placed alongside verbal communication. Every single cultural fact may be approached and understood as a message assembled on the basis of codes. Therefore, a general theory of society coincides with general semiotics (cf. Eco, 1968). 'The study of any sign-system becomes useful for the study of any other [...] especially because, in studying one system or the other, what one studies is *fundamentally the same thing*' (ibid.: 69).

This becomes clearer when we consider that in the case both of verbal and nonverbal messages semiotics addresses the same problems – the work that produces them and that makes exchange and communication possible. For example, Claude Lévi-Strauss (cf. 1958) used the categories of linguistics in his studies on the rules of matrimony and kinship systems, offering a truly formidable example of the application of conceptual frameworks elaborated in relation to verbal communication to nonverbal communication. Rossi-Landi (2003 [1968]) attempted the opposite procedure: he applied categories elaborated in the study of nonverbal communicative sign structures, that is, the categories of economics in its classical phase with David Ricardo and Marx, to verbal language.

Ontologic and Methodologic Structuralism in Semiotics

All the same, there exists a substantial difference between the approach adopted by Lévi-Strauss and that by Rossi-Landi to problems of communication: it is an example of the difference between ontologic structuralism – criticized by Eco in his book *La struttura assente* ('The absent structure,' 1968) – and methodologic structuralism.

Lévi-Strauss's reasoning is questionable when he justifies his application of categories proper to language to his studies on nonverbal communication in terms of 'recurrent hymns to the *esprit humain*.' This implies reference to a universal unconscious activity and universal structures of the *esprit humain*. As Eco explains, some texts by Lévi-Strauss appeal to "a fundamental combinatory principle at the basis of all codes [...]," to "an elementary mechanism rooted in the functioning of the human mind [...]." Thus the universe of social relations, myths, and language, becomes "the setting for a game which takes place behind man's back and in which he is not involved, if not as an obedient voice which lends itself to expressing a complicated game which surpasses and annuls him as a responsible subject" (296). In other words, human individuals do not determine their own relations; on the contrary, they are 'related' passively according to the universal laws and structures they obey.

Instead, Rossi-Landi recognized human beings as the concrete subjects of history, the responsible agents of culture and communicative systems, which enabled him to formulate his thesis of the **homology** between verbal and nonverbal communication. Linguistic work and nonlinguistic work necessary to the production of physical objects may be placed on the same level. "If we don't want to admit that something *human* can exist for man without the intervention of man himself, we must adhere to the principle that every wealth or value, however understood, is the result of a work that man has performed and can repeat" (Rossi-Landi, 2003 [1968], Eng. trans.: 36).

A global structural semiotic approach must explicate the human being's specific dual character as *loquens* and *laborans*, i.e., the recognized fact that human beings are constructed historically through the production of tools and verbal messages. Methodological structuralism is connected with a homological method which enables us to formulate a unitary definition of the human being as a speaking and working animal, such that these two modes of social behavior are considered homologous.

This structural homology between material and linguistic production throws light on the concept of double articulation in language as described by André Martinet (1960). Transition from the articulation of sentences into words and monemes to the articulation of monemes into phonemes proves to be oriented in the opposite direction from the real processes of linguistic production (cf. Rossi-Landi, 2003 [1968], Eng. trans.: 119–121, 158–159). Speakers carry out linguistic work – phylogenetically and ontogenetically – proceeding from sounds that are initially disarticulate, but that are subsequently articulated into words, phrases, and sentences of increasing complexity. The structural theory of double articulation assumes that language is no more than a formal machine, while neglecting the facts of experience and the needs upon which linguistic behavior depends. It puts aside the problem of the generation of meaning and use of sentences, limiting its approach to describing their constituent parts. With Rossi-Landi we may observe that when we analyze or 'order' (as Martinet says) sentences into words and monemes and monemes into phonemes, we are not saying anything about 'semantic content' which is 'added' at the level of sentences, as opposed to the level of monemes and words, and at the level of monemes as opposed to the level of phonemes. Nothing is said about the human operations through which semantic content is produced. The work of analyzing sentences into words and monemes, and monemes into phonemes, is abstract analytical work that has very little to do with the social linguistic work through which the objects studied by the linguist are originally formed. Nor must abstract analytical work be mistaken for social linguistic work.

An interdisciplinary semiotic approach, or an intersemiotic translation of different approaches to social structures in different fields is favored by a homological scheme for linguistic production, as proposed by Rossi-Landi (cf. ibid.: 118–152). Unlike 'double

articulation theory,' the latter is potentially interdisciplinary because it is intentionally **pre**disciplinary. To refer to a precategorial level with respect to the categorial 'already-made-world' means to question the idea of science as something that has already been formed and defined and to criticize scientific specialization when it loses sight of the human needs for which it was originally developed.

The Human Being's Structuralist Approach as a Semiotic Animal

Any scientific approach considers the world – reality – as being in constant movement and transformation and, in view of this, formulates its hypotheses and laws. The formulation of laws is possible because movements and transformations present constants, states of balance, and systematic and essential aspects, which belong to 'reality,' or the 'world.' This balance or stability in phenomena and in relations among the elements of reality (in organic or inorganic nature and in culture) together with relatively autonomous and isolated systems of elements have an objective existence and consequently constitute the potential objects of our knowledge. Therefore, we must discover and determine not only the laws of the dynamics of movement and development in reality, but also the structural laws of relatively isolated systems in relative balance. We must study the structures of dynamics and the dynamics of structures. Not only is the study of both types of law founded, but such a complementary study contributes to a global image of reality. If we wish to study the (genetic, causal) laws of something's development, we must establish what this 'something' is; and, therefore, it becomes necessary to know the laws of its structure (coexistent, morphologic structure). This gradual knowledge of structure is just as essential as knowledge of the genesis and development of the objects under study.

This is why knowledge of coexistential, morphologic laws is among the most ancient in human history: it dates backs to when human beings learned to differentiate between a plant and another, an animal and another, that is, when they learned to articulate reality on the basis of the capacity to recognize signs, to identify coexistent features which differentiate things. In this sense, as a semiotic animal, the human being is also, as maintains the Polish philosopher Adam Schaff, a 'structuralist animal.' Structuralism is not only the trend of a semiotician, but also of humans as humans.

Structures and Processes

H van de Koot, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

If one wants to capture the properties of a complex object, it is necessary to specify the relations between the elements of which it consists. The sum of these relations is called the structure of the object.

In linguistics, words, sentences, and even entire discourses and texts are thought of as structured objects. Structures are used to specify the internal organization of linguistic objects at every level of description, be it phonological, morphological, syntactic, semantic, or pragmatic. For example, the string *A child broke a window* may be assigned the constituency structure in (1), which assigns a label to individual words and specifies how they are grouped together, a semantic structure along the lines of that in (2), and a prosodic representation like that in (3), where ω represents a prosodic word, Φ a prosodic phrase, I an intonational phrase, and U an utterance.

(1)

(2) past(break(child21,window45))

(3) $[_U[_I[_\omega$ a child$]$ $[_\Phi[_\omega$ broke$]$ $[_\omega$ a window$]]]]$

Structures are also used to express the internal syntactic, semantic, and phonological properties of words. For example, the verb *break* specifies an event in which *x* causes *y* to enter some state, which might be expressed by a lexical semantic structure as in (4), where each lambda-bound variable represents a semantic role.

(4) break: λy λx CAUSE(x,STATE(y))

The internal phonological structure of the word *window* could be represented as in (5).

(5)

A linguistic process can be thought of as an operation (or rule) that maps one linguistic structure to another. For example, many linguistic theories formalize passivization as a process that changes the way in which a verb's semantic roles (such as Agent and Patient) are mapped onto syntactic structure.

Similarly, processes may affect semantic structures in various ways. For example, the process of suppression can map the semantic representation of the transitive verb *break* in (4) into the one-argument variant in (6), which corresponds to the semantics of *break* in example (7).

(6) break: λy $\exists$x CAUSE (x,STATE(y))

(7) The window broke.

Structures and processes stand in an intricate relation to each other. It is natural to think of a process as being triggered by certain signature properties of a representation; in the absence of these properties, the process cannot apply. For example, because passivization promotes an OBJECT to a SUBJECT, it cannot apply to a verb like *sleep* that lacks an object to begin with:

(8) John slept.

(9) *There was slept.

If one wants to capture the properties of a complex object, it is necessary to specify the relations between the elements of which it consists. The sum of these relations is called the structure of the object.

In linguistics, words, sentences, and even entire discourses and texts are thought of as structured objects. Structures are used to specify the internal organization of linguistic objects at every level of description, be it phonological, morphological, syntactic, semantic, or pragmatic. For example, the string *A child broke a window* may be assigned the constituency structure in (1), which assigns a label to individual words and specifies how they are grouped together, a semantic structure along the lines of that in (2), and a prosodic representation like that in (3), where ω represents a prosodic word, Φ a prosodic phrase, I an intonational phrase, and U an utterance.

(1)

(2) past(break(child21,window45))

(3) $[_U[_I[_\omega$ a child$]$ $[_\Phi[_\omega$ broke$]$ $[_\omega$ a window$]]]]$

Structures are also used to express the internal syntactic, semantic, and phonological properties of words. For example, the verb *break* specifies an event in which *x* causes *y* to enter some state, which might be expressed by a lexical semantic structure as in (4), where each lambda-bound variable represents a semantic role.

(4) break: λy λx CAUSE(x,STATE(y))

The internal phonological structure of the word *window* could be represented as in (5).

(5)

A linguistic process can be thought of as an operation (or rule) that maps one linguistic structure to another. For example, many linguistic theories formalize passivization as a process that changes the way in which a verb's semantic roles (such as Agent and Patient) are mapped onto syntactic structure.

Similarly, processes may affect semantic structures in various ways. For example, the process of suppression can map the semantic representation of the transitive verb *break* in (4) into the one-argument variant in (6), which corresponds to the semantics of *break* in example (7).

(6) break: λy $\exists$x CAUSE (x,STATE(y))

(7) The window broke.

Structures and processes stand in an intricate relation to each other. It is natural to think of a process as being triggered by certain signature properties of a representation; in the absence of these properties, the process cannot apply. For example, because passivization promotes an OBJECT to a SUBJECT, it cannot apply to a verb like *sleep* that lacks an object to begin with:

(8) John slept.

(9) *There was slept.

For this reason, linguistic processes are often formalized as a pair, consisting of a structural description and a structural change. Modern constraint-based theories have replaced this kind of formalization by a more modular approach in which very general operations are kept in check by a collection of abstract principles.

A final word of caution. Generative linguists take linguistic structures to be mental objects and assume that these structures are formed and modified by linguistic processes of some sort. However, because linguistic theories generally abstract away from actual language processing, it is an open question to what extent linguistic processes are a direct reflection of mental computation.

Sturge–Weber–Dimitri Syndrome and Language

S Rémillard and H Cohen, Université du Québec à Montréal, Montréal, Canada

© 2006 Elsevier Ltd. All rights reserved.

The association of cerebral leptomeningeal angioma and facial nevus flammeus in the territory of the first branch of the trigeminal nerve ipsilateral to the angioma is known as Sturge–Weber syndrome (SWS). The cases with absence of a facial angioma are usually considered to be variants of the syndrome. This is a rare congenital neurocutaneous syndrome of unknown origin that occurs in both sexes with a frequency of approximately 1 per 50 000 (e.g., Comi, 2003). Sturge first described this disorder in 1879. In 1922, Weber described a similar clinical case and advocated the use of the term 'encephalotrigeminal angiomatosis' to describe it. It is characterized by leptomeningeal angiomatosis, glaucoma, and ipsilateral facial capillary hemangioma (port-wine stain) in the ophthalmic division of the trigeminal nerve (Aicardi, 1992). The facial nevus flammeus is present in 98% of children with SWS and it is visible at birth (Sujansky and Conradi, 1995b). It usually affects the upper eyelid and the forehead. The stain is caused by an overabundance of capillaries just beneath the surface of the affected skin. The angioma is typically located on the parietal and occipital lobes. It has been suggested that the angioma results from the failure of the primitive cephalic venous plexus to regress and properly mature in the first trimester of development (Comi, 2003). Normally, this vascular plexus forms in the sixth week and regresses at approximately the ninth week of gestation.

SWS is also characterized by neurological manifestations, which include focal or diffuse seizures (Kramer *et al.*, 2000), abnormal cerebral glucose metabolism (Lee *et al.*, 2001; Maria *et al.*, 1998; Pfund *et al.*, 2003; Pinton *et al.*, 1997), enlargement of the choroid plexus (Guermazi *et al.*, 2000), progressive atrophy and calcification of the brain (Comi, 2003; Jay, 2000; Shamoto and Chugani, 1997), and recurrent stroke-like episodes (see Thomas-Sohl *et al.*, 2003, for a review of clinical symptoms and management). Hemianopia, progressive hemiparesis, motor deficits, developmental delay, and mental retardation are other dysfunctions associated with this neurological disorder. Mental retardation is present in approximately 50% of children with SWS (Sujansky and Conradi, 1995a) and clinical severity of signs and symptoms varies widely from one patient to another (Maria *et al.*, 1998).

It has been hypothesized that two main complications of SWS may explain the progressive neurological deficits associated with the disorder: the occurrence of seizures and cerebral ischemia. Thus, repeated seizure activity is associated with developmental delay, permanent hemiparesis, and mental retardation. In addition, venous stasis and recurrent episodes of venular thrombosis may be responsible for neurological deteriorations (cerebral calcification, gliosis of the cortex and white matter) and postnatal hemispheric atrophy (Comi, 2003; Kramer *et al.*, 2000; Portilla *et al.*, 2002).

Epilepsy affects over 80% of the children with SWS (Sujansky and Conradi, 1995a; Ville *et al.*, 2002). In a majority of children, onset occurs during the first year of life. Of the children who did not develop seizures during their first 2 years of life, only 14% developed seizures subsequently. It has been suggested that onset of seizures during the first 2 years of life and the presence of uncontrollable seizures are responsible for the developmental deterioration of previously normally functioning children with SWS (Roach, 1992). Thus, according to Sujansky and Conradi (1995a), later age of seizure onset is a favorable prognostic indicator. Contrary to these observations, Kramer *et al.* (2000) showed that cognitive delay is significantly correlated with seizure intensity, rather than the age of onset.

When seizures are unihemispheric and intractable to medication, hemispherectomy is strongly

For this reason, linguistic processes are often formalized as a pair, consisting of a structural description and a structural change. Modern constraint-based theories have replaced this kind of formalization by a more modular approach in which very general operations are kept in check by a collection of abstract principles.

A final word of caution. Generative linguists take linguistic structures to be mental objects and assume that these structures are formed and modified by linguistic processes of some sort. The association of cerebral leptomeningeal angioma and facial nevus flammeus in the territory of the first branch of the trigeminal nerve ipsilateral to the angioma is known as Sturge–Weber syndrome (SWS). The cases with absence of a facial angioma are usually considered to be variants of the syndrome. This is a rare congenital neurocutaneous syndrome of unknown origin that occurs in both sexes with a frequency of approximately 1 per 50 000 (e.g., Comi, 2003). Sturge first described this disorder in 1879. In 1922, Weber described a similar clinical case and advocated the use of the term 'encephalotrigeminal angiomatosis' to describe it. It is characterized by leptomeningeal angiomatosis, glaucoma, and ipsilateral facial capillary hemangioma (port-wine stain) in the ophthalmic division of the trigeminal nerve (Aicardi, 1992). The facial nevus flammeus is present in 98% of children with SWS and it is visible at birth (Sujansky and Conradi, 1995b). It usually affects the upper eyelid and the forehead. The stain is caused by an overabundance of capillaries just beneath the surface of the affected skin. The angioma is typically located on the parietal and occipital lobes. It has been suggested that the angioma results from the failure of the primitive cephalic venous plexus to regress and properly mature in the first trimester of development (Comi, 2003). Normally, this vascular plexus forms in the sixth week and regresses at approximately the ninth week of gestation.

SWS is also characterized by neurological manifestations, which include focal or diffuse seizures (Kramer *et al.*, 2000), abnormal cerebral glucose metabolism (Lee *et al.*, 2001; Maria *et al.*, 1998; Pfund *et al.*, 2003; Pinton *et al.*, 1997), enlargement of the choroid plexus (Guermazi *et al.*, 2000), progressive atrophy and calcification of the brain (Comi, 2003; Jay, 2000; Shamoto and Chugani, 1997), and recurrent stroke-like episodes (see Thomas-Sohl *et al.*, 2003, for a review of clinical symptoms and management). Hemianopia, progressive hemiparesis, motor deficits, developmental delay, and mental retardation are other dysfunctions associated with this neurological disorder. Mental retardation is present in approximately 50% of children with SWS (Sujansky and Conradi, 1995a) and clinical severity of signs and symptoms varies widely from one patient to another (Maria *et al.*, 1998).

It has been hypothesized that two main complications of SWS may explain the progressive neurological deficits associated with the disorder: the occurrence of seizures and cerebral ischemia. Thus, repeated seizure activity is associated with developmental delay, permanent hemiparesis, and mental retardation. In addition, venous stasis and recurrent episodes of venular thrombosis may be responsible for neurological deteriorations (cerebral calcification, gliosis of the cortex and white matter) and postnatal hemispheric atrophy (Comi, 2003; Kramer *et al.*, 2000; Portilla *et al.*, 2002).

Epilepsy affects over 80% of the children with SWS (Sujansky and Conradi, 1995a; Ville *et al.*, 2002). In a majority of children, onset occurs during the first year of life. Of the children who did not develop seizures during their first 2 years of life, only 14% developed seizures subsequently. It has been suggested that onset of seizures during the first 2 years of life and the presence of uncontrollable seizures are responsible for the developmental deterioration of previously normally functioning children with SWS (Roach, 1992). Thus, according to Sujansky and Conradi (1995a), later age of seizure onset is a favorable prognostic indicator. Contrary to these observations, Kramer *et al.* (2000) showed that cognitive delay is significantly correlated with seizure intensity, rather than the age of onset.

When seizures are unihemispheric and intractable to medication, hemispherectomy is strongly

recommended. This type of surgery is used in an attempt to control seizures and to prevent neurological deterioration (Kossoff *et al.*, 2002). Generally, bilateral angiomatosis is a contraindication to epilepsy surgery because a more diffuse region of epileptogenesis, which is not resectable, is more probable and the seizure prognosis may thus be unfavorable (Arzimanoglou *et al.*, 2000; Roach *et al.*, 1994). Nevertheless, according to some authors, epilepsy surgery in SWS should not be used too restrictively (Tuxhorn and Pannek, 2002). Tuxhorn and Pannek presented two bilateral cases of SWS that showed good seizure control and remission of epileptic encephalopathy after functional hemispherectomy.

Language development in SWS has not been well studied. Nevertheless, a few case studies have shown that language impairments associated with this syndrome result principally from epilepsy and following hemispherectomy. Vargha-Khadem *et al.* (1997) described the case of a 9 year old boy diagnosed with SWS affecting the left hemisphere, in which seizure activity is the cause for arrested speech development. This boy, named Alex, experienced his first epileptic episode 6 days after birth. Despite having normal hearing, Alex did not develop speech, and his utterances, at 33 months of age, were still limited to babbling. Furthermore, his intellectual development was globally delayed. Between the ages of 4 and 8 years, Alex attempted to communicate with gestures. At age of 8 years 6 months, Alex underwent a successful left hemispherectomy. Interestingly, 10 months after surgery, Alex suddenly began to develop speech and, by age 10, could converse with copious and appropriate speech. This child achieved remarkable linguistic competence with an isolated right hemisphere and he speaks clearly and fluently with grammatically correct sentences. However, in the domain of receptive language, Alex showed poor comprehension of more complex grammatical sentences, as assessed by the Token Test (De Renzi and Vignolo, 1962) and the Clinical Evaluation of Language Functions-Revised (CELF-R; Semel *et al.*, 1987). Other cognitive dysfunctions have been noted in Alex's case, such as reading, writing, and arithmetic. At age 13, his performance in these cognitive areas was still at the basal level (i.e., <6 years).

Mariotti *et al.* (1998) described the linguistic abilities of a woman with SWS who underwent early removal of her left hemisphere, at age 3. Extensive assessment of her linguistic abilities was conducted when she was 20. In contrast to Alex's case, her performance, when compared to mentally retarded controls matched for age, education, and IQ, showed fluent spontaneous speech with intact pragmatic abilities, normal articulation, prosody, and phrase length, and grammatically correct sentences. Reading and writing on copy were also normal, although writing on dictation was slightly impaired. As in Alex's case, however, she showed a marked impairment in more complex syntactic comprehension of sentences, low IQ, and poor memory span.

These observations in the case of SWS and hemispherectomy indirectly suggest a necessary integrity of the left cerebral hemisphere to adequately process morphosyntactic aspects of language. However, not all authors agree with this interpretation on the issue of cerebral hemispheric specialization of function (e.g., Bishop, 1988; Mariotti *et al.*, 1998; Vargha-Khadem *et al.*, 1997). Rather, they attribute the observed deficits to a low IQ and limited verbal memory span in children with SWS. Mariotti *et al.* (1998) suggested that failure of syntactic tasks could be merely the expression of a generic cognitive impairment (such as poor lexical knowledge) and not of specific linguistic damage. Thus, it is unclear whether the language dysfunction seen in SWS can be ascribed to a low IQ and poor working memory.

Sturtevant, Edgar Howard (1875–1952)

S-H Seong, University of Bonn, Bonn, Germany

© 2006 Elsevier Ltd. All rights reserved.

Edgar H. Sturtevant was born in Jacksonville, Illinois. He studied at the University of Chicago (receiving his Ph.D. in 1901 with a dissertation on Latin case forms) and later became an assistant professor of classical philology at Columbia University in New York. In 1923 he joined the linguistics faculty at Yale University, which soon acquired a reputation in the United States for its strong linguistics program. In 1924, he was a member of the organizing committee for the founding of the Linguistic Society of America (LSA), in which Leonard Bloomfield and George M. Bolling actively participated.

Sturtevant played a major role at the Linguistic Institutes in the promotion of the study of phonetics, research on Native American languages, and field work on the Modern American English dialects.

Most of Sturtevant's works focus on historical linguistics and classical philology. When it was speculated that the Hittite language (ca. 2000 to 1200 B.C.) was related to the Indo-European language family, Sturtevant became especially absorbed in the investigation of its genealogy. In this endeavor, as was customary at the onset of modern scientific linguistics of that time, the recovery of prehistoric linguistic systems and regularity of linguistic change were sought by the comparative method. His first major paper on this subject was 'On the position of Hittite among the Indo-European languages,' published in *Language* (1926). His position was that Hittite exhibits more archaic traits than the normally reconstructed forms for Indo-European, and hence both Hittite and Indo-European have an earlier common ancestor stage, namely, Indo-Hittite. On the other hand, it was shown that Hittite could be grouped into the Indo-European family after it was demonstrated by Kuryłowicz in 1927 that the language preserved distinct reflexes of the segments postulated in de Saussure's internal reconstructive hypothesis. Sturtevant dedicated himself to the phonological and morphological investigations of the Hittite language.

It should be stressed that while most linguists in the United States at that time were students of historical philology, Sturtevant was a significant figure who contributed to the shift from historical to non-historical

Edgar H. Sturtevant was born in Jacksonville, Illinois. He studied at the University of Chicago (receiving his Ph.D. in 1901 with a dissertation on Latin case forms) and later became an assistant professor of classical philology at Columbia University in New York. In 1923 he joined the linguistics faculty at Yale University, which soon acquired a reputation in the United States for its strong linguistics program. In 1924, he was a member of the organizing committee for the founding of the Linguistic Society of America (LSA), in which Leonard Bloomfield and George M. Bolling actively participated.

Sturtevant played a major role at the Linguistic Institutes in the promotion of the study of phonetics, research on Native American languages, and field work on the Modern American English dialects.

Most of Sturtevant's works focus on historical linguistics and classical philology. When it was speculated that the Hittite language (ca. 2000 to 1200 B.C.) was related to the Indo-European language family, Sturtevant became especially absorbed in the investigation of its genealogy. In this endeavor, as was customary at the onset of modern scientific linguistics of that time, the recovery of prehistoric linguistic systems and regularity of linguistic change were sought by the comparative method. His first major paper on this subject was 'On the position of Hittite among the Indo-European languages,' published in *Language* (1926). His position was that Hittite exhibits more archaic traits than the normally reconstructed forms for Indo-European, and hence both Hittite and Indo-European have an earlier common ancestor stage, namely, Indo-Hittite. On the other hand, it was shown that Hittite could be grouped into the Indo-European family after it was demonstrated by Kuryłowicz in 1927 that the language preserved distinct reflexes of the segments postulated in de Saussure's internal reconstructive hypothesis. Sturtevant dedicated himself to the phonological and morphological investigations of the Hittite language.

It should be stressed that while most linguists in the United States at that time were students of historical philology, Sturtevant was a significant figure who contributed to the shift from historical to non-historical

linguistics in the United States. This position is already visible in his earlier publication, *Linguistic change* (1917). Sturtevant discusses the relation of speech and writing: "[i]n the experience of most of us conversation is trivial and ungrammatical, while written language has some value and is usually correct. . . . As a matter of fact, however, whether we think of the history of human speech in general or of the linguistic experience of the individual speaker, spoken language is the primary phenomenon, and writing is only a more or less imperfect reflection of it." For Sturtevant, linguistics was a discipline that primarily deals with spoken language. It should be noted that de Saussure's distinction between diachrony and synchrony was also being introduced in Europe at that time. In recognition of his contribution to historical linguistics Sturtevant was elected LSA president for 1931.

> Thanks to words, we have been able to rise above the brutes; and thanks to words, we have often sunk to the level of the demons.
>
> Aldous Huxley, *Adonis and the alphabet*, 1956 (John Gross, 1987: 280).

The Etymology of the Word 'Style'

Etymologically, the word 'style' derives from Latin *stilus*, originally meaning an ancient writing instrument made of metal, wood, or bone. It had a sharp-pointed end for scratching letters on a wax tablet and a blunt end for erasing them; in obsolete English, it was a 'style.' (This spelling with [y] is due to the erroneous notion that it represents the Greek word *stûlos*, meaning 'column.') In an endearing piece on how children should be taught how to write, Quintilian (c. 35–c. 95 A.D.) says:

> As soon as the child has begun to know the shapes of the various letters, it will be no bad thing to have them cut as accurately as possible upon a board, so that the pen (*stilus*) may be guided along the grooves. Thus mistakes such as occur with wax tablets (*ceris*) will be rendered impossible; for the pen will be confined between the edges of the letters and will be prevented from going astray (*Institutio oratoria*, 1920: I.I.27).

The *Oxford English dictionary* has this 14th-century entry: "Seinte Barnabe his body was found in a den . . . with Þe gospel of Mathew Þat he hadde i-write wiÞ his owne stile." (Note the etymologically correct spelling.)

Considering its present-day widespread usage in all kinds of contexts of everyday life, this restricted meaning of 'style' must have gone through a remarkable semantic development. The successive steps in this development are likely to have been the metonymical extension from 'an instrument for writing' to 'a manner of writing,' first in the literal sense of 'a writer's characteristic way of shaping letters,' and next in the figurative and deeper sense of 'a writer's characteristic mode of expression in terms of effectiveness, clarity, beauty and the like.' Though in the five canons of classical Latin rhetoric (see below) style is termed *elocutio*, the metonym *stilus* is also regularly used in the same sense. For instance, in *Brutus*, Cicero (1939) says about the orations of a certain Gaius Claudius that they are so splendid 'that they would seem almost to have been written by an Attic pen' (*ut paene Attico stilo scriptae esse videantur*) (XLV.167). From the context it is obvious that '*Attico stilo*' means here 'in Attic style.' Of course, the translator's word 'pen' is also a metonym for 'a particular

linguistics in the United States. This position is already visible in his earlier publication, *Linguistic change* (1917). Sturtevant discusses the relation of speech and writing: "[i]n the experience of most of us conversation is trivial and ungrammatical, while written language has some value and is usually correct. . . . As a matter of fact, however, whether we think of the history of human speech in general or of the linguistic experience of the individual speaker, spoken language is the primary phenomenon, and writing is only a more or less imperfect reflection of it." > Aldous Huxley, *Adonis and the alphabet*, 1956 (John Gross, 1987: 280).

The Etymology of the Word 'Style'

Etymologically, the word 'style' derives from Latin *stilus*, originally meaning an ancient writing instrument made of metal, wood, or bone. It had a sharp-pointed end for scratching letters on a wax tablet and a blunt end for erasing them; in obsolete English, it was a 'style.' (This spelling with [y] is due to the erroneous notion that it represents the Greek word *stûlos*, meaning 'column.') In an endearing piece on how children should be taught how to write, Quintilian (c. 35–c. 95 A.D.) says:

> As soon as the child has begun to know the shapes of the various letters, it will be no bad thing to have them cut as accurately as possible upon a board, so that the pen (*stilus*) may be guided along the grooves. Thus mistakes such as occur with wax tablets (*ceris*) will be rendered impossible; for the pen will be confined between the edges of the letters and will be prevented from going astray (*Institutio oratoria*, 1920: I.I.27).

The *Oxford English dictionary* has this 14th-century entry: "Seinte Barnabe his body was found in a den . . . with Þe gospel of Mathew Þat he hadde i-write wiÞ his owne stile." (Note the etymologically correct spelling.)

Considering its present-day widespread usage in all kinds of contexts of everyday life, this restricted meaning of 'style' must have gone through a remarkable semantic development. The successive steps in this development are likely to have been the metonymical extension from 'an instrument for writing' to 'a manner of writing,' first in the literal sense of 'a writer's characteristic way of shaping letters,' and next in the figurative and deeper sense of 'a writer's characteristic mode of expression in terms of effectiveness, clarity, beauty and the like.' Though in the five canons of classical Latin rhetoric (see below) style is termed *elocutio*, the metonym *stilus* is also regularly used in the same sense. For instance, in *Brutus*, Cicero (1939) says about the orations of a certain Gaius Claudius that they are so splendid 'that they would seem almost to have been written by an Attic pen' (*ut paene Attico stilo scriptae esse videantur*) (XLV.167). From the context it is obvious that '*Attico stilo*' means here 'in Attic style.' Of course, the translator's word 'pen' is also a metonym for 'a particular

style of writing,' as in the well-known saying 'The pen is mightier than the sword.'

The Proliferation of Style

However, the semantic history of style does not end here, because in later centuries it was transferred to a great many other contexts. Perhaps this happened because style belongs to the domain of language and its offshoots speaking and writing, and it is a well-known fact that mapping from this domain to other areas of experience is quite common. This is illustrated by examples like 'the **language** of flowers'; '**speaking** colors'; '**telling** figures'; 'their absence **spoke** volumes,' etc. It may have been in this way that style gained widespread currency outside the domain of language. Indeed, a particular style may be attributed not only to painting, architecture, music, or fashion, but to practically any other mental or physical activity, for example, 'a pen-and-ink sketch in Rembrandtesque style'; 'a revival of the Gothic style'; 'Schubert's *Overture in Italian style*'; 'a flamboyant style of dress'; 'an autocratic style of management'; 'a country-style dinner'; 'an aggressive style of play,' etc.

Furthermore, the term 'style' resulting from this semantic transfer may also be used in a kind of absolute sense to refer to a particular type, make or shape of something, e.g., 'these shoes come in all sizes and styles,' or to describe a superior quality or manner as such, e.g. 'the team has simply been beaten by style'; 'the restaurant is a statement of taste and style in fusion,' etc. In sum, a brief questioning of an internet search engine will show that style is omnipresent in practically all domains of human existence.

Some Tentative Thoughts on the Nature of Style

Behind the external features of style, as illustrated by the above-mentioned examples, one usually suspects some conscious or unconscious intention and significance. In other words, it is generally assumed that style has a phenomenal as well as a conceptual element, which, though they can be distinguished, are at the same time inseparably interconnected. For instance, Rembrandt's chiaroscuro technique in his painting and Philip Larkin's repeated use of metonyms in his poetry are clearly recognizable phenomenal aspects of their art, which simultaneously convey a deep conceptual significance. In other words, it seems that style is concerned with the mutually creative interplay between perceptible form and intangible content.

All this also implies that in principle style is associated with humans either as individuals or as a group linked to a specific context of place, time, and culture, and that normally the notion of style is not applied to entities or things that are not the result of some human action. Therefore, unless it is a case of personification, it seems odd to speak of the style of, for instance, a gust of wind or a thunderstorm. Significantly, this sense of human consciousness and agency implies that the attribution of a particular style to some artifact, action, or performance entails all kinds of underlying social, cultural, and ideological implications (Verdonk, 2002: 18–21).

Apart from the above tentative ideas about style, it has so far proved to be very difficult to define it as an abstract concept. Again, this is a problem for nonlinguistic and linguistic style alike (Wales, 2001: 370–372). Indeed, style as the equivocal interface between form and content, or in stronger terms, style as the confrontation between a perceived outward appearance and some assumed intrinsic value, has never ceased to trouble the human mind. At the same time, it is ironic that style is a creation of that very same mind.

For a possible answer to the question of how style ever came into being as an invaluable asset of the human mind, I will now briefly discuss its relationship with rhetoric.

Rhetoric-cum-Style: the Earliest Beginnings

Because style in language is often related to rhetoric and sometimes even equated with it, I will first give a brief account of the potential effect of what might be called proto- or primary rhetoric on the urge for survival of the human species and their social-cultural evolution. This is followed by a somewhat more detailed discussion of the emergence of classical rhetoric in Western culture and of some of its long-lived intellectual and artistic achievements, interspersed with occasional excursions to present-day views whenever this seems relevant and useful.

Rhetoric, then, may be assumed to be as old as human communication. In a general sense, it may be described as a cognitive and emotive drive in people to use language in such a manner as to impress or emotionalize others and then persuade them to adopt or reject a certain viewpoint, or to undertake or refrain from a particular course of action. The target of this persuasive process may also be one's own self. A famous literary example of self-persuasion is the noble Brutus in Shakespeare's *Julius Caesar,* II.1.10–34, who argues himself into the conviction that Caesar must die.

From an evolutionary perspective the ultimate source of this basic impulse, and thus of rhetoric, is likely to have been the instinct of self-preservation, and as such rhetoric may be supposed to have contributed to the preservation of the human species (Kennedy, 1998: 4). The persuasive force of this primary rhetoric was inevitably conditioned not only by **what** was said, i.e., the content, but also by **how** it was said, i.e., the form. Now, this formal aspect or manner of expression, which is inseparably interconnected with its content, and at the same time causally related to a relevant social and communicative context, is the natural predecessor of what later evolved into the concept of style.

In the course of human history, the evolution from relatively simple to more complex cultures raised the level of sophistication of this innate rhetorical-cum-stylistic capacity, which also extended to oral forms of literary expression. For instance, centuries before the introduction of rhetoric as a theory, the culture of the ancient Greeks had a long-established tradition of oral poetry on heroic and mythological topics in which forceful eloquence, i.e., rhetoric, is a stylistic hallmark. Particularly, in the great Homeric epics the *Iliad* and the *Odyssey* (8th century B.C.), verbal agility is invariably put on a par with physical prowess. For example, in the *Iliad*, when Achilles has resentfully withdrawn from the fighting in the siege of Troy, the old charioteer Phoenix points out to him the two vital qualifications of the Homeric hero: 'It was to teach you all these things, to make **a speaker** of you and **a man of action** . . . .' (*Iliad*, Homer, 1950: X.443; my emphasis). After Homer's poetry had been written down in the course of the 7th century B.C., the oratorical style of the epic heroes became a favorite object of study in the training schools for rhetoricians and had a strong influence on the conception of the ideal orator in Greek and Roman civilization (Kennedy, 1999: 6). For instance, some 800 years later, Cicero recalls the same Homeric tale about Phoenix teaching the young Achilles how to be 'an **orator** and **man of action** too' (*De oratore*, Cicero, 1942: III.XV.57).

The Rise of Classical Rhetoric-cum-Style in the Greek City-States

Long before the invention of writing, the extraordinary potency of language must have been a constant source of fascination, because after literate cultures had internalized writing, the rhetorical and stylistic uses of language were often the first topics of theoretical study. Indeed, as Ong has put it, "writing . . . did not reduce orality but enhanced it, making it possible to organize the 'principles' . . . of oratory into a scientific 'art'" (1982: 9). This is exactly what happened in major ancient cultures such as Mesopotamia, Egypt, Palestine, China, India, and Greece (Kennedy, 1998: 115–140). In Western culture, the ancient Greeks developed an elaborately structured system aimed at teaching public speech and written composition, which under the name of 'rhetoric' (short for 'the art of rhetoric') was inherited by classical Rome and became a dominant factor in European culture for more than two thousand years. Obviously, cross-cultural or comparative research work is needed to establish the correspondences and differences between Western and non-Western rhetoric. See, for example, Kennedy (1998).

The theory and practice of rhetoric-cum-style particularly flourished in the 5th and 4th centuries B.C., when new democratic systems of government were introduced in the ancient Greek city-states, of which Athens became the most important. In the political (from Greek *polis* 'city') and judicial institutions of these dawning democracies, vigorous and persuasive self-expression was held to be an essential prerequisite for any position of power and influence. The ensuing social ambition created a booming market not only for itinerant teachers of oratory and rhetoric, known to philosophical history as the Sophists, but also for the establishment of fully fledged schools that provided an education for those who aspired to a place of prominence in public life.

Aristotle's *Art of Rhetoric*

This accumulated practice of oratory brought forth a great many rhetorical handbooks that aimed at developing a theory of eloquence, called in Greek *technē rhētorikē*. Though this phrase is usually rendered as 'the art of rhetoric' (perhaps under the influence of the Latin phrase *ars rhetorica*), Plato, and also Aristotle, had a wider conception of *technē*, which embraced our concepts of art, technique, and skill (Lawson-Tancred, 1991: 264). Initially, the Sophists had defined rhetoric as 'the art of persuasion,' which Aristotle in his seminal treatise *The art of rhetoric* (c. 335 B.C./1926) subsequently changed into the more theoretical formulation "[the function of rhetoric] is not so much to persuade, as to find out in each case the existing means of persuasion" (I.I.14). This implies that if in a particular case the persuasion is unsuccessful, the theory of rhetoric as a whole remains valid.

In addition to promoting rhetoric to a respectable branch of philosophy, Aristotle also treats the process of persuasion as a human and social reality, claiming that the use of the body in self-defense is now superseded by the use of rhetoric because humans are essentially rational beings (I.I.12). Besides, if it is

argued that this verbal capacity can cause a great deal of harm too, it may be countered that this goes for all good and useful things, if they are badly used (I.I.13). Therefore, Aristotle's book may be seen as an apologia for rhetoric to repair the damage to its reputation, for which the Sophists were generally held responsible. Their then leader was Gorgias (c. 483–375 B.C.), who had skeptical views about the possibility of getting to the truth through reason and about the validity of traditional ethical notions such as right and wrong. See Wardy (1996) for an interesting study of Gorgias. These views were ardently propagated by his followers, but unfortunately the instrument they used for it was rhetoric. Of course, there were many, as there would be now, who fully realized the dangers of an accomplishment that could argue that what is wrong is right. It is therefore not unlikely that, as a consequence of this realization, the term 'sophistic' and at least one of the popular senses of 'rhetoric' have become infected by pejorative overtones ever since.

Gorgias must have been a well-known figure in Athens, because Plato named his dialogue *Gorgias* (c. 384 B.C.) after him. It is the earliest example of a bitter attack on rhetoric, which Plato saw as the source of all corruption. Socrates, one of the fictional characters in the dialogue, refuses 'to give the title of art to anything irrational' (465) and voices a number of fierce criticisms: rhetoric is 'no art at all'; it is 'a sort of knack gained by experience' (462); it is 'a branch of something which certainly isn't a fine or honorable pursuit' (463); and it is to be placed 'among the subdivisions of pandering' (463) (Plato, 1960). The question of whether Aristotle wrote his *Rhetoric* in response to Plato's *Gorgias* will probably always remain unanswered.

Techniques of Persuasion: *Ethos/Pathos/Logos* Interconnected by Style

Indeed, whereas previous handbooks had focused mainly on the sophistic persuasive tricks of the oratorical trade, Aristotle's book was the first to provide a theory of public speaking, or civic discourse, founded on psychological, logical, and moral principles. For instance, he divides the means of persuasion or 'proofs' (*pisteis*) into two types (I.II.2):

1. Nontechnical or inartistic proofs such as sworn testimonies, tortures (*sic*), contracts, and the like, which already exist and need not be furnished by the art (*technē*) of the persuader.
2. Technical or artistic proofs that have to be invented by the persuader using the principles of the art of rhetoric.

These artistic proofs, in their turn, can be of three kinds (I.II.3–6; repeated in II.I.1–4):

1. The proof derived from the trustworthy character (*ethos*) of the persuader, that is, the ethical and psychological appeal that the speaker makes to the audience by creating a sympathetic image of him or herself. As Cockcroft has observed: . . . '*ethos*: that is, our character, [includes] our goodwill, our morality, our competence and our emotional authenticity, as perceived by the persuadee' (2003: 43–44).
2. The proof derived from the emotions (*pathos*) induced in the audience. It deals with the gamut of sentiments that the persuader must arouse in the listeners to trigger their favorable reactions. In addition, as Nash has aptly put it, during this process of swaying the audience 'There comes a point . . . when the silent partners in the dialogue – the listeners, the readers – are no longer being told; they start to tell themselves, and in doing so help to shape the rhetoric that persuades them' (1989: 197).
3. The proof derived from logical argumentation (*logos*), which is not about establishing the objective general truth as in hard science, but about finding arguments that rest on generally accepted principles and will therefore be acceptable to the audience (I.I.12).

Incidentally, perhaps Aristotle's motivation for his third proof suggests one of the reasons why rhetoric (and, by implication, style) has ever developed in the human mind. Most things in this world cannot be worded unequivocally, nor are they generally agreed on. Persuasion is then a last resort. This, by the way, fits in with modern discourse studies, which have challenged the idea that there is a direct correspondence between language and reality. Besides, this view of words and the world brings rhetoric and literature more closely together (Hesse, 1992: 21–22).

Returning to the three techniques of persuasion, it will be noticed that they are closely interrelated. Thus, the *logos* of a speech is only effective if it tunes in with the audience's *pathos*, which, in turn, is to a large extent the outcome of the speaker's *ethos*. In this interconnectedness, a specific use of language, i.e. style, plays a crucial role: for example rhetorical figures, like schemes, i.e., patterns of conspicuous regularity of form such as parallelism, repetition, antithesis, etc., which intensify meaning without actually changing it; and, tropes, i.e., patterns involving a conspicuous change of the standard meaning, such as metaphor, metonymy, irony, etc. All these and other figures may well reinforce the emotional appeal of an argument, which must at the same time adequately reflect the speaker's ethical stance as well as the emotions of the audience.

A Modern Instance of how *Ethos, Pathos,* and *Logos* are Interconnected by Style

The epigraph of this article appears to be a case in point:

> Thanks to words, we have been able to rise above the brutes; and thanks to words, we have often sunk to the level of the demons. (Aldous Huxley)

This is a straightforward piece of rhetoric in which the author's *ethos* (I have the professional and moral experience to speak with authority on this issue), his *logos* or argument (language can be used with good and evil intentions), and the readers' presumed *pathos* (the painful awareness that we are naturally inclined to misuse our gift of language), are closely interconnected and reinforced by specific features of style.

The style is sententious because it relies on antithesis, a classical figure of thought that contrasts certain ideas expressed in contrasting words in a formal parallel structure (Wales, 2001: 24). The clash of ideas is set forth by the two metaphorical images 'we have been able to rise above the brutes' and 'we have often sunk to the level of the demons,' which effectively refresh our experience that language can be both a blessing and a curse. The formal parallelism is brought about by some conspicuous repetitive patterns such as the lexical phrase 'thanks to words,' with the first occurrence properly introducing the beneficial effect of language, while the second occurrence is ironically linked up with its harmful use. There is also marked syntactic repetition. The maxim is made up of one compound sentence consisting of two coordinate clauses with basically the same syntactic functions, linked by the conjunction 'and.' One would have expected the antithetical conjunction 'but.' This, however, would not have been compatible with the irony of the repeated phrase 'thanks to words.'

Additionally, the repeated personal pronoun 'we' is rhetorically very effective. It is an instance of its so-called presumptive use, implying that the writer assumes that the reader shares the same values. A further implication of this inclusive 'we' may be that it appeals to the collective voice of universal conscience (Wales, 1996: 62–63).

And, last but not least, Huxley has chosen a very appropriate text type or genre for his rhetorical lament. It is an aphorism, a classical genre, which is usually defined as a pithily and often authoritatively expressed maxim usually relating to some abstract matter.

The Earliest Introduction to Psychology in a Discourse Situation

In his *Rhetoric* Aristotle also provides the earliest introduction to psychology in a discourse situation. By exploring the emotions (*pathos*) that may be awakened in the audience, such as anger, calm, friendship, enmity, fear, confidence, shame, pity, jealousy, etc., he allows the persuader a useful insight into the mechanics of human motivation (II.II–XI). This is followed by a discussion of the effects on the human character of the three ages (youth, prime, old age) and of fortune (birth, wealth, power). These potential characteristics of the audience are useful for the persuader to know with a view to adapting his character (*ethos*) accordingly (II.XII–XVII). Interestingly, the pictures Aristotle presents of youth, prime, and old age appear to be a reflection of the common stereotypical characters of antiquity that can also be seen in the comedies of Menander and his Roman imitators, Plautus and Terence (Kennedy, 1991: 163). The tradition they represented is responsible for the form and style taken by English comedy up to the 19th century, and perhaps even by many present-day sitcoms.

Genre and Style

Because deploying arguments is not only a matter of logic but also of the objective of the persuasion, Aristotle divides rhetoric into three genres or areas of activity in relation to the type of audience: deliberative (political), forensic (judicial), and epideictic (concerned with praise or blame) (I.II.22–III.4). These three genres of oratory became canonical and persisted throughout the long history of rhetoric and even beyond.

The concept of genre, in the sense of a culturally specific type of discourse, like these three kinds of rhetorical speeches or, for that matter, a newspaper article, a business letter, an aphorism, a poem, etc., is highly relevant to style. This is because speakers and writers tend to adapt their language, i.e., their style, in a particular type of discourse to the conventions imposed on it by its social role and setting. This, however, is a reciprocal process, because listeners and readers normally are also tuned in to these socialized stylistic conventions. Thus, once they have made themselves familiar with a particular genre, they have usually also developed a sense of what kind of style they can expect, and therefore they adjust their listening or reading accordingly. On the other hand, both producers and consumers of texts also know that there is not always a one-to-one correspondence between genre and style. For example, novels, advertisements, newspapers, mock epics, etc., may feature an overlapping of different styles. Now, looking at genre from this broad stylistic perspective, some scholars of stylistics have adopted the view that the conventional distinction between 'literary' and 'nonliterary' texts is

in fact unnecessary (Fowler, 1996: 94). For an interesting and plausible cognitive linguistic approach to the role of genre in language and style, see Steen (2002a: 183–209).

Aristotle's Ambivalent View on Style

In the very last sentence of Book II of his *Rhetoric* Aristotle writes: 'It only remains to speak of style and arrangement' (II.XXVI.5). Up to this point Aristotle has not yet said a word about style (*lexis*, in his terminology), though it must have been uppermost in his mind when he was devising his theory of the three modes of persuasion. But he delays a discussion of style to the last, only coming to it in chapters 1–12 of Book III. In fact, there is a theory that Books I–II and Book III may originally have been separate works, and that the final sentence of Book II was added later as a linkage when the three books were made a single treatise (Kennedy, 1991: 302). Anyway, Aristotle, somewhat surprisingly, begins by saying that he has so far ignored the matter of style because in rhetoric the emphasis must be first of all on the logical invention of the most effective arguments, and also because 'it is thought vulgar' (III.I.5). Here his old teacher Plato must have been looking over his shoulder, prompting him that all that should matter is evidence and logic, while style is just empty words. However, then Aristotle goes on to say that since the whole business of rhetoric is to sway opinion, he must pay attention to style, not because it is right but because it is necessary, and also because 'it is of great importance owing to the corruption of the hearer' (III.I.5–6). At this moment it seems that the Sophists have taken Plato's place as his guide, because from here on he discusses style at great length.

Some Highlights from Aristotle's Stylistic Precepts

The main virtues of style are clarity and appropriateness (III.II.2; the latter is repeated in III.VII.2–11). To be clear the speaker or writer should steer a middle course between ordinary and poetic language as appropriate to the subject and the occasion. On the other hand, it is permissible and even recommendable to give one's language a certain strangeness, 'for men admire what is remote, and that which excites admiration is pleasant' (III.II.3). In poetry this often occurs and there it is appropriate. If this artifice is used in prose, it must be concealed, because one must avoid speaking artificially instead of naturally; 'for that which is natural persuades, but the artificial does not' (III.II.4–5).

It will be noted that more than two thousand years later Aristotle's observation that the language of poetry is characteristically 'strange' was to be literally repeated by the Russian Formalists with the phrase *ostranenie* 'making strange.' See Wales (2001: 135) for 'estrangement' and Short (1996: 10–79) for a detailed discussion of the related stylistic concept of foregrounding.

Consequently, the orator must also make proper use of metaphors because they provide clarity, pleasure, and unfamiliarity. "[They] should therefore be derived from what is beautiful either in sound or in signification, or to sight, or to some other sense" (III.II.6–13). Simile, for that matter, is like metaphor. It belongs to poetry, but it is also useful in prose, though with restraint (III.IV.2–3).

In later chapters of his book, Aristotle adds, among others, the requirements of purity or grammatical correctness (III.V.5–7), rhythm (III.VIII), and ornamentation (III.X–XI). With regard to the latter, he returns again to his favorite figure, the metaphor (III.XI), putting a special emphasis on visual metaphors 'which set things before the eyes.' Such metaphors signify activity (*energeia*) as, for instance, in 'The spear-point sped eagerly through his breast' from Homer's *Iliad*.

Finally, the last chapter (III.XII) on style contains a discussion on its suitability to the genres he discussed in Book I: political, judicial, and epideictic. Political oratory resembles a rough sketch and needs little precision, because the larger the crowd, the less the attention paid. The style of judicial oratory should be much more meticulous, involving the smallest degree of rhetoric. Finally, the epideictic style is most like that of written composition.

In subsequent sections of this essay, Aristotle's stylistic precepts of clarity, appropriateness, purity, and ornamentation will be discussed in the light of speech act theory and cognitive linguistics.

The Audience Factor in Classical Rhetoric and Beyond

In spite of Aristotle's earlier mentioned skepticism about the moral integrity of his listeners, his rhetoric and style are definitely audience-directed, in that he evaluates every rhetorical and stylistic device not only in terms of what it **is** but also of what it **does** to the listener. This audience factor and, by extension, the reader factor, completes a threefold communicative framework in classical rhetoric comprising the interaction between a speaker (or writer), a text and an audience (reader). This communicative triangle fits in with some relatively recent developments in literary theory, stylistics, education, composition, textual studies, and discourse studies. However, it should be

noted that the huge theoretical apparatus of rhetoric does not mention a single word about the possibility of an active role of the audience (reader) in the process of meaning production. The audience was only the passive object of the intended persuasive effects of the text.

This situation remained unaltered when the Renaissance humanists rediscovered Aristotle, Cicero, and Quintilian, and also throughout the following centuries things remained as they had always been. Even the most influential literary theories formulated in the first three decades of the 20th century perpetuated this passivity of the reader. In Russian Formalism, the Prague Linguistic Circle, Practical Criticism, and New Criticism, the formal autonomy of the text was fully maintained and there was no role for the reader in the activation of meaning. This situation was to last until the 1970s and 1980s when postformalist theories were advanced, in which a text was no longer seen as an autonomous object but as a discourse, that is, as a contextualized sociocognitive interaction in which meaning is not unidirectional but rather a matter of negotiation between speakers or writers on the one hand and listeners or readers on the other. See Widdowson (1975 and 1992), Fowler (1981), and Carter and Simpson (1989).

The Decline of Greek Rhetoric as a Practice

In 338 B.C. the Greek city-states were subjected to Macedonian rule, which put an end to the democratic institutions in Athens and therewith to the practice of political and forensic rhetoric. Only epideictic oratory could survive; but this tended to degenerate into tedious panegyrics on the Macedonian kings. Paradoxically, though the practice of rhetoric had virtually come to an end, its theory was considerably expanded in the following 250 years of what is now called the Hellenistic period. One of the leading figures in this development was Theophrastus (c. 370–c. 285 B.C.), who had been a pupil of Aristotle and had succeeded him as head of Aristotle's Lyceum. Though his writings have not survived, it is known from other sources that he developed some of Aristotle's ideas considerably and, as the works of some later Roman writers show, his influence on rhetoric was greatest in the areas of style and delivery.

In parallel with this growth in theory, rhetorical training in hypothetical situations became firmly established in the educational system, that is, in the elite establishments for the sons of the well-to-do. Obviously, in the absence of a professional practice, this instruction in rhetoric became entirely formal and, in fact, an end in itself.

The Roman Takeover

Ironically, the history of the rise of rhetoric as a system during the budding democracy of the Greek city-states repeated itself, under broadly similar circumstances, in the Roman Republic in the middle of the 2nd century B.C. During the political deliberations in the Senate and the legal actions in the law courts, the spoken word was predominant and eloquence became an indispensable weapon. So it was an ideal opportunity for the appropriation of the well-tried devices of persuasion provided by the theory of rhetoric and style as devised by the Greeks, and *technē rhētorikē* was Latinized as *ars rhetorica*.

The Ranking of Style in Roman Rhetoric

The Roman rhetoricians regarded style as the most difficult task for the orator (Quintilian, 1921: VIII.13). Thinking up what to say and arranging it is one thing, but finding the most effective words for it is another! It was again Quintilian who was most outspoken, maintaining that without the power of style 'all the preliminary accomplishments of oratory are as useless as a sword that is kept permanently concealed within its sheath' (1921: VIII.15).

Whereas Aristotle, for reasons of his own, relegated the treatment of style to the last part of his *Rhetoric*, the Latin rhetoricians unambivalently rank style (*elocutio* in their terminology) as the third of the five canons or divisions of rhetoric: (1) Invention; (2) Arrangement; (3) Style; (4) Memory; and (5) Delivery. There is no attempt, though, to integrate these elements into a coherent whole. In his most influential work, *De oratore* (55 B.C.), Cicero comes up with a refreshing formulation of these five components of oratory:

> And, since all the activity and ability of an orator falls into five divisions, I learned that he must first hit upon what to say [*inventio*]; then manage and marshal his discoveries, not merely in orderly fashion, but with a discriminating eye for the exact weight, as it were, of each argument [*dispositio*]; next go on to array them in the adornments of style [*elocutio*]; after that keep them guarded in his memory [*memoria*]; and in the end deliver them with effect and charm [*actio*]. (The Latin interpolations are mine.) (Cicero, 1942: I.xxxi.142–143)

The Troubled Relationship between Content and Form (Style)

The metaphorical phrase 'to array them in the adornments (*vestire atque ornare*) of style' raises again the ever recurrent issue of the divide between content (*ratio rerum*) and form or style (*ratio verborum*). It is

a mechanical metaphor suggesting that style is something added. Similar metaphors include 'clothing,' 'dress,' 'coat,' and 'colors,' which have been fashionable for many centuries. For instance, after more than sixteen hundred years, in 1666, in his *Preface to Annus Mirabilis*, John Dryden still gives a full Ciceronian account of the five divisions of rhetoric, describing style as follows: "the third is Elocution, or the Art of clothing and adorning that thought so found [...] in apt, significant and sounding words."

On the other hand, in direct contradiction to his 'dress and ornament' metaphor, the very same Cicero, elsewhere in his *De Oratore* (III.XVI.61), dubs a separation between form and content as an 'undoubtedly absurd and unprofitable and reprehensible severance between the tongue and the brain.' In point of fact, in Greek and Roman rhetoric the divide between the **what** and the **how** was conditional and artificial. It probably originated in rhetorical pedagogy requiring students to analyze texts in terms of content and form. This, too, turned out to become a long-standing tradition. Thus, in 1512 Erasmus of Rotterdam wrote a textbook entitled *De copia verborum ac rerum* ('On the abundance of verbal expressions and ideas'), in which he asked his students to produce as many formal variations as possible of all kinds of sentences. He himself sets the example by coming up with one hundred and fifty different stylistic versions of the Latin sentence '*Tuae literae me magnopere delectarunt*' ('Your letter has pleased me very much'). Obviously, some of the resulting versions will be silly and unusable, but this kind of teaching experiment will increase the student's awareness of the stylistic flexibility of language (Corbett, 1990: 461–462).

Style as Motivated Choice

It will be noted, by the way, that Erasmus's exercise might be seen as a kind of forerunner of one of the present-day popular definitions of style, namely style as choice. In this view, style is seen as the making of conscious and unconscious choices of certain linguistic forms and structures in preference to others that could have been chosen but were not. Obviously, every linguistic choice that is made is codetermined by a wide variety of contextual considerations, such as the genre of text, time, place, the nature of the communicative context, etc. See Wales (2001: 370–372) and Verdonk (2002: 5–6).

These choices, which may also be regarded as stylistic markers, are assumed to be made on particular levels of the structure of language (the text) in relation to the contextual and communicative situation (pragmatics and discourse). Though there are various models distinguishing different numbers of levels, here I will make use of the following six-level model of linguistic structure and discourse. It will be understood that in reality language and discourse are not so neatly organized as they are represented in this diagram, which therefore only serves as a basic groundwork for analysis and discussion. For a detailed account of style in relation to the levels of language and discourse, see Simpson (2004: 5–8).

1. Graphology (typographical features: typeface, punctuation, etc.)
2. Phonology (sounds, rhythm, rhyme, etc.)
3. Lexis (vocabulary)
4. Syntax; grammar (sentence structure, use of tenses, etc.)
5. Semantics (considerations of textual meaning)
6. Pragmatics; discourse (features of external context; communicative situation).

In fact, all these levels are interconnected and interdependent. For example, Charles Dickens's apparently simple choice to put quotation marks, from the level of graphology, around the opening lines of his novel *Hard Times* (1988: 47), has far-reaching consequences on the level of pragmatics and discourse:

> 'Now, what I want is, Facts. Teach these boys and girls nothing but Facts. Facts alone are wanted in life. Plant nothing else, and root out everything else. You can only form the minds of reasoning animals upon Facts: nothing else will ever be of any service to them. This is the principle on which I bring up my own children, and this is the principle on which I bring up these children. Stick to Facts, sir!'

Though it is a brief example, it features a great many stylistic markers of which, given the scope of this article, I can only point out a few. To begin on the level of discourse, it is a representation of free direct speech of one of the characters. It is called 'free' because the only evidence of the narrator's presence are the quotation marks. Thus, there is no clause in which the narrator reports the speech (as 'He said'), which on the level of discourse would indicate that the character is held in leash by the narrator. On the contrary, by choosing free direct speech, the narrator delegates the point of view to the character, leaving him (assuming for the moment it concerns a man) to speak for himself. This furthermore implies that the narrator does not describe the character but lets him describe himself.

At various points in the text, reference is made to persons, places, and time by means of grammatical and lexical words or phrases like 'I,' 'you,' 'sir,' 'these boys and girls,' and the present tenses of verbs, for example, 'want,' 'is,' 'bring up,' etc. Now, prompted

by their experience of the real world and their knowledge of the stylistic conventions of fiction, readers will understand these linguistic expressions as representations of the people, place, and time in the story, and will act on them as cues to imagine themselves as participating in the situation of the fictional world of the discourse. By persuading readers to assume a presence in the world of the novel, these textual cues or deictics (from Greek 'pointing'), as they are technically called, prompt the following important questions: Who is telling the story? Who is the narrator or character talking to? Where and when do the events take place? And, importantly, from whose point of view is the story told? The deictics in a text may answer this last question, because human beings are cognitively primed to relate space, time, and persons in the world around them to their own subjective position, that is, to view them from their own point of view. A quick look again at the deictics in the above text will show that so far everything in the story world is experienced from the character's perspective, which was already confirmed by the representation of the character's words in free direct speech.

Shifting again to the levels of syntax, lexis, and graphology in relation to other relevant levels, the reader will be struck by the strident shortness of the sentences, and the insistent and monotonous repetition of the word 'Facts,' each time written with a capital, probably to mark the character's emphatic pronunciation of the word. This emphasis becomes even stronger through the repetitive use of the excluding phrases 'nothing but,' 'alone,' and 'nothing else' used in relation to the speaker's cherished 'Facts.'

On the interconnected levels of lexis, semantics, pragmatics, and discourse, when the speaker talks insensitively about the boys and girls as 'reasoning animals,' using the degrading metaphoric images 'plant nothing else, and root out everything else,' as if their minds were the fertile soil in which his Facts could be sown, he dehumanizes the children depriving them of their imagination and emotions.

Finally, back to the level of pragmatics and discourse: the reader may notice the irony in the speaker's insistent reference to **facts** in the opening passage of a work of **fiction**. Anyway, a long time ago the above stylistic choices held enough fascination for this reader to be persuaded by the character's awful rhetoric to enter this fictional world, and to read and reread this great novel.

The Content/Style Issue has Become a Critical Tool and a Literary Game

As is only to be expected, the content/style issue has never ceased to haunt people's minds. For while content and style are definitely assumed to be one, they are still frequently being discussed in terms of two separate entities, which creates the paradox of simultaneously postulating a oneness and a 'twoness.' As it is, this paradoxical thinking has provided considerable scope for creativity in that it has become an evaluative tool in the hands of literary critics as well as a source of inspiration for poets and writers. The following is a perfect illustration of this. In the introduction to her book *The breaking of style*, the American critic Helen Vendler writes:

> To represent style, I use the word 'body' (rather than the perhaps more customary image of dress) because I want to emphasize the inextricable relation of style to theme. Yeats's bravado in 'A Coat' with respect to doffing his 'old embroideries' – 'There's more enterprise / In walking naked' (*Collected poems*, 1956: 125) – suggests, misleadingly, that one *can*, in poetry, walk naked – and that one can easily slough off a style. Nothing could be further from the truth (1995: 2).

This is the poem referred to:

A Coat
I made my song a coat
Covered with embroideries
Out of old mythologies
From heel to throat;
But the fools caught it,
Wore it in the world's eyes
As though they'd wrought it.
Song, let them take it,
For there's more enterprise
In walking naked. (W.B. Yeats, *Collected poems*.)

The poet playfully states his intention that he will remove all stylistic ornamentation from his poetry and allow the content to 'walk naked.' With this metaphor of divestment, Yeats jocularly announces a shift in his earlier style, while at the same time upbraiding certain fellow poets for imitating it. It is evident from the 'coat' metaphor that the poet is making artistic use of the classical style/content divide, and by giving a free rein to his imagination he creates from it his own literary world.

It may be true that Vendler's 'body' metaphor emphasizes less strongly than the classical 'dress' metaphor that style is an additional element, but she does not escape from the inherent paradox mentioned earlier. In fact, the confusion is complete when she appears to miss the ironical point of Yeats's literary game, and criticizes him for doing something she has just done herself. Besides, this poem has become an autonomous literary event, which Vendler cannot use to tackle Yeats on a difference of opinion she has with him in the 'real' world.

The Three Levels or Types of Style (*genera dicendi*)

Though the long lists of precepts in their handbooks may give a different impression, the classical rhetoricians did not aim at a general normative model of style. Thus, in his *Institutio oratoria*, Quintilian writes that the reading of poets, historians, and philosophers is of great service to the orator, though he must not follow these writers in everything because of the obvious differences between the various genres (1922: X.I.27–36). Besides, in oratory, too, there are three different genres to be observed and therewith three different styles: judicial, political, and epideictic. And even within the same genre, the orator must be able to vary his style: "... some things require a gentle and others a violent style, some require an impetuous and others a calm diction, while in some cases it is necessary to instruct and in others to move the audience, in all these instances dissimilar and different methods being necessary" (X.II.23).

However, in spite of the fact that the rhetorical theorists gave the practicing orator a lot of leeway to choose a particular style, they still felt the need to establish a broad framework of three different levels or types of oratorical style:

1. The grand style (*genus grave* or *grande*) features a smooth and ornate arrangement of impressive words. It is an artful style, with figures of speech, and suited to the conclusion of an important oration.
2. The middle style (*genus medium*) is somewhat more relaxed without descending to the most ordinary prose. It is suited to descriptive passages in an oration, its effect being mainly esthetic.
3. The low or plain style (*genus humile*) is brought down to the most ordinary speech of every day. It is suitable for the narrative part in an oration.

This three-part division had already been devised by the Greek Theophrastus, in a work now lost, and was later adopted by the anonymous author of *Rhetorica ad Herennium*, dating from the first century BC and wrongly attributed to Cicero until the 15th century (Cicero, 1954: IV.VIII–XI), and by Cicero in *Orator* (1939: VI.20–XIII.42).

In literature the grand style was regarded suitable for epic and tragedy, the middle style for didactic poetry, and the low style for comedy and pastoral poetry. Virgil's works are often used as an illustration of the three styles: the epic *Aeneid*, the didactic *Georgics*, and the pastoral *Eclogues*. It is striking that, on the one hand, this theory is concerned with particular types of style, and on the other hand with a division into three social classes: warriors (*Aeneid*), peasants (*Georgics*), and shepherds (*Eclogues*). In European literature this tradition continued at least until the Romantic period.

The Four Virtues of Style (*virtutes dicendi*)

In addition there are four virtues of style that are common to all three types. (Compare Aristotle's stylistic precepts discussed earlier.) These, too, were first classified by Theophrastus and later developed in the anonymous *Rhetorica ad Herennium* (Cicero, 1954: IV.XII.17–LV.69), by Cicero in *De oratore* (1942: III.IX.37–LV.212) and Quintilian in *Institutio oratoria* (1921 and 1922: VIII–XI). These stylistic qualities may be briefly summarized as follows:

1. Correctness or purity (*Latinitas*) is mainly concerned with the correct use of language and is therefore on the borderline between grammar and rhetoric. The language must be clear, elegant, and well adapted to produce the desired effect.
2. Clarity (*perspicuitas*) is of course closely allied to correctness. There must be propriety in our words, their order must be straightforward, and the sentences must not be too long. The language will be approved by the learned and clear to the uneducated. There must be no obscurities or ambiguities.
3. Decorum (*aptum*) or the quality of appropriateness is not only a matter of style but of every aspect of an oration. Our style must be adapted to every condition in life, to every social rank, position or age, and a similar distinction must be made in respect of place, time, and audience. Quintilian also adds a moral dimension: it is becoming 'to all men at all times and in all places ... to act and speak as a man of honor' (*Institutio oratoria,* 1922: XI.I.14), which seems to be an early precursor to Buffon's celebrated 18th century dictum '*Le style, c'est l'homme même*.'
4. Ornament (*ornatus*) is concerned with the decorative aspects of style, in particular the figures, which are aimed at adding force to the intended effect and affect. 'Figures' is a general term for any linguistic device or pattern as a result of which meaning is either changed or intensified. The rhetorical figures are traditionally divided into the following:

1. Figures of speech, which, in turn, are subdivided into the following:
   1.1. Tropes (Greek *tropos* 'turn') in which words or phrases are used in such a way that their ordinary meaning is conspicuously changed.

Examples include simile, metaphor, metonymy, and oxymoron, and also figures like hyperbole, irony, and litotes, owing to which meaning cannot be taken literally.
Leech (1969: 74) defines tropes as foregrounded irregularities of content.

1.2. Schemes (Greek *skhēma* 'form, figure') are figures in which words are arranged into particular lexical, syntactic, or phonetic patterns that intensify or enhance meaning without actually changing it. Examples include repetition, chiasmus, antithesis, and zeugma. Schematic patterns of sound include alliteration and assonance.
Leech (1969: 74) defines schemes as foregrounded repetitions of expression.

2. Figures of thought are often loosely associated with the figures of speech, though they are different in their form and function. They have a pragmatic function at sentence or text level in the presentation of the argument or theme to the listener or reader, e.g., rhetorical questions; apostrophe; amplification; and antithesis (Wales, 2001: 152–154). For an example of antithesis, see the analysis of Huxley's aphorism.

The Virtues of Style in Terms of Speech Act Theory

One might argue that rhetoric is concerned with speech in action, so that the virtues of style, which are clearly audience oriented, could provide an interesting point of comparison with speech act theory (Austin, 1962; Searle, 1969). Thus, the stylistic qualities of correctness and clarity are obviously required for a meaningful locutionary act, i.e., the act of uttering a meaningful linguistic expression. The quality of decorum corresponds with the appropriate context, or the so-called felicity conditions, on which the success of the illocutionary act, i.e., the act of conveying some communicative purpose, depends. This is in the present case the rhetorical act of persuasion (Fahnestock, forthcoming).

However, speech act theory is less suited to deal with the stylistic quality of ornament involving figurative language, because it perpetuates the traditional view that such language is deviant and that understanding such language is different from ordinary linguistic processing. Now, recent research in cognitive linguistics has shown that not only is a lot of our language figuratively structured, but so also is much of our cognitive processing. So people understand, i.e., conceptualize, their everyday experiences in figurative terms through metaphor, metonymy, irony, oxymoron, etc., and these codes underlie the way we think, reason, and imagine (Gibbs, 1994: 5). Therefore, it is more profitable to consider the stylistic quality of ornament from the perspective of cognitive linguistics.

The Rhetorical Figures Considered from the Point of View of Cognitive Linguistics

In various writings Aristotle, Cicero, and Quintilian make some casual remarks about the ordinariness of metaphor in everyday language. For instance, Aristotle observes that 'we all use metaphors in conversation' (*Rhetoric*, 1926: III.II.3–6), while Cicero writes that they 'were brought into common use for the sake of entertainment, for even country folk (*sic*) speak of "jeweled vines"' (*De oratore*, 1942: III.XXXVIII.155). And, finally, Quintilian notices that metaphor is 'often employed unconsciously or by uneducated persons (*sic*)' (*Institutio oratoria*, 1921: VIII.VI.4–5). Now, if they had taken this view more seriously with regard to all genres of discourse, they would have been much closer to the present-day view that metaphor, and by implication all figurative language, is an omnipresent phenomenon that forms an integral part of our way of thinking and all uses of language. But, as we know, the ancient rhetoricians rejected the idea of figurative language being 'ordinary' when used for decorative and affective stylistic purposes in rhetoric and literary discourse. To put it differently, the above wording of the stylistic virtue of 'ornament' means that figuration is mainly a matter of embellishing literal language to create a particular stylistic effect.

For instance, the rhetoricians would see the antithetical metaphors 'we have been able to rise above the brutes' and 'we have often sunk to the level of the demons' in Huxley's aphorism as a creative and ornamental way of expressing literal equivalents, for instance, 'we have been able to live as civilized human beings' and 'we have often been cruel and destructive.' In such a view language and mind are independent of each other and both intrinsically literal. This traditional approach to figurative language has been dominant in the humanities in Western culture for thousands of years.

However, in cognitive linguistics things are just the other way round: tropes and schemes, and figures of thought, are no rhetorical byproducts of a process of objective thinking of an independent mind; rather, they are a reflection of how people **construe** their knowledge and experience of the world around them (Lee, 2001: 6–7; my emphasis).

For example, a metaphor (from Greek 'transference') is essentially a device that involves conceptualizing

one domain of experience in terms of another, which implies that every metaphor is founded on a source domain and a target domain. Thus, in the metaphoric images 'we have been able to rise above the brutes' and 'we have often sunk to the level of the demons,' the source domain is people's everyday physical experience of all kinds of spatial orientations, in this case UP-DOWN. The target domains are abstract concepts like VIRTUE ('living a decent life') and DEPRAVITY ('being cruel and destructive'). (Note that it has become a convention to use small capitals for the concepts that underlie a metaphorical expression.) It will be observed that the former concept gets an 'upward' orientation and the latter a 'downward' orientation. This example also shows that source domains tend to be relatively concrete areas of experience and target domains to be more abstract (Lee, 2001: 6).

Note that in Western culture this type of metaphor is quite common. They are based on a mundane source domain related to a particular spatial orientation of the human body and a target domain referring to some abstract concept. For example, HAPPY IS UP; SAD IS DOWN ('My spirits **rose**.' 'He **fell** into a depression.'); HEALTH AND LIFE ARE UP; SICKNESS AND DEATH ARE DOWN ('He is in **top** shape.' 'He is **sinking** fast.' 'He **dropped** dead.'); GOOD IS UP; BAD IS DOWN ('Things are looking **up**.' 'Things are at an all-time **low**.'). (Lakoff and Johnson, 1980: 14–21; Kövecses, 2002: 35–36.)

This cognitive process of using a simpler concept to get to grips with a more difficult one yields what is called a 'conceptual metaphor,' such as HAPPY IS UP. Here is another example: RELATIONSHIPS ARE BUILDINGS ('They have **built** a solid relationship'). Conceptual metaphors must be distinguished from linguistic metaphors, which consist of linguistic elements such as 'built' that derive from the language used for the simpler conceptual source domain such as BUILDINGS in the foregoing example. In this connection, Heywood *et al.* (2002: 35–54) and Steen (2002b: 17–33) make interesting reading.

Of course, the language of writers and poets may be expected to be more creative on this score, but in essence they make use of the same figures and schemes as the nonprofessionals. As the above examples show, metaphors are so common in everyday talk that we hardly seem to notice them. Consider how we ordinarily speak or write about time: 'We are **wasting** time'; 'We have no time **to lose**'; 'We are **running out of** time.' These are all metaphorical expressions or, more precisely, they reveal how in our everyday experience we conceive of time as something that is in short supply, which may result in a conceptual metaphor like TIME IS A LIMITED RESOURCE. When Andrew Marvell writes:

> But at my back I always hear
> Time's winged chariot hurrying near.
> And yonder all before us lie
> Deserts of vast eternity. ('To His Coy Mistress')

he is using the same experiential conceptual metaphor, be it, of course in a much more creative fashion. It is equally important to realize that we, in turn, use the same conceptual metaphor TIME IS A LIMITED RESOURCE in making sense of Marvell's poem (Gibbs, 1994: 6–8). For an interesting cognitive linguistic approach to metaphor in literary prose, see Weber (1995: 32–44) discussing Doris Lessing's short story 'To Room Nineteen.'

Another important figure of speech, or in cognitive linguistic terms a figurative mode of thought, is metonymy (Greek 'name change'; the Latin term is *denominatio*). Metonymy occurs when the name of one thing is given to another thing with which it is closely associated, within one and the same conceptual domain. Consider, for instance, the sentence 'I heard the **piano**.' Obviously, only sounds can be heard, not objects. What is conveyed is that I heard, not the piano as such, but a sound coming from the piano (Taylor, 2002: 112). In cognitive linguistic terms, a metonym involves a process in which one conceptual entity provides mental access to another conceptual entity, within the same domain, in this case THE INSTRUMENT FOR THE PRODUCT (Kövecses, 2002: 145). Some more examples include 'He's got a **Picasso** in his den' (PRODUCER FOR PRODUCT), 'The **sax** has the flu today' (OBJECT USED FOR USER), and '**Exxon** has raised its prices again' (INSTITUTION FOR PEOPLE RESPONSIBLE) (Lakoff and Johnson, 1980: 38).

In cognitive linguistics, the rhetorical figure synecdoche (Greek 'taking together') is regarded as a special case of metonymy. In synecdoche, a part of something is used to refer to the whole, or (more rarely) the whole is used to signify a part. Metonymic concepts like THE PART FOR THE WHOLE are so common in everyday speech that we hardly notice them. Consider, for example, 'All **hands** on deck!' for 'sailors,' 'The **White House** has plans for the economy' for 'the whole system of the U.S. government,' etc. Advertising frequently uses this type of metonymy, e.g., 'Drink your **Heineken** now!' (PRODUCER FOR PRODUCT).

Furthermore, like metaphors, metonyms are the mainstays of novelists and poets. Consider how the poet Philip Larkin uses a string of synecdochic images to evoke the depressingly huge supermarket catering to the trivial needs in the humdrum lives of the working classes:

> The large cool store selling cheap clothes
> Set out in simple sizes plainly
> (Knitwear, Summer Casuals, Hose,

In browns and greys, maroon and navy)
Conjures the weekday world of those

Who leave at dawn low terraced houses
Timed for factory, yard and site. (Philip Larkin, 'The Large Cool Store')

After the enormous amount of attention that has been paid to metaphor in cognitive linguistic research, it appears that now metonymy has come into focus. Interestingly, the hypothesis has been put forward that metonymy is even more fundamental to cognitive and linguistic processes than metaphor, to the extent that many conceptual metaphors are founded on metonymic stimuli. See Panther and Radden (1999) and Steen (2004).

Cognitive Stylistics (Also Called Cognitive Poetics)

One of the valuable spinoffs from cognitive linguistic research is cognitive stylistics, also called cognitive poetics. It is an interdisciplinary study of how readers process literary texts, or perhaps better still, 'of what happens when a reader reads a literary text' (Stockwell, 2002: 5). Probably the main reason many students of style find fresh inspiration in cognitive linguistics is that this approach does not regard language as a separate and independent cognitive faculty, as it is assumed to be in Chomskyan linguistics. On the contrary, cognitive linguists hold that there is a close interactive and meaningful relationship between linguistic and other cognitive abilities, which include thinking, imagination, learning, memory, perception, attention, emotion, reasoning, and problem solving. All these abilities enable humans to survive and make sense of the world around them. From this it follows that cognitive linguistics is thoroughly experiential from a physical, social, cultural, ideological, and emotive point of view.

To put it differently, cognitive linguists seek to explain the formal manifestations of language not only in terms of the cognitive abilities that are their plausible providers, but also in terms of the communicative or discursive functions that such empowered language structures perform (Taylor, 2002: 8–9). Yet another source of inspiration for stylistics and poetics is that cognitive linguistics was (and still is) developed in relation to other cognitive sciences, such as cognitive anthropology, psychology, psycholinguistics, and artificial intelligence. This interdisciplinary approach has yielded completely new concepts, theories, and ideas that will enable students of style and poetics to analyze, describe, and rationalize 'the effects of literary texts on the mind of the reader.' See Gavins and Steen (2003: 2).

In addition to the foregoing cognitive analyses and interpretations of metaphor, metonymy, and other rhetorical figures, cognitive stylistics and poetics also draw on other cognitive concepts, such as schema theory and frames for research into readers' comprehension of texts (Semino, 1997; Emmott, 1997), the concept of figure and ground to account for readers' response to foregrounding (Emmott, 2002; Stockwell, 2002), and a lot of other theoretical concepts from the cognitive sciences that cannot be discussed here because of lack of space. The following collections of essays deal with a wide variety of examples of how cognitive stylistics and poetics can be fruitfully combined with theories and insights from cognitive linguistics and other cognitive disciplines: Csábi and Zerkowitz (2002), Gavins and Steen (2003), and Semino and Culpeper (2002), which all show how the cognitive sciences have breathed new life into stylistics and poetics.

Rebirth of Rhetoric-cum-Style?

To go by the title of an interesting book published nearly fifteen years ago (Andrews, 1992), rhetoric appears to have been reborn. However, in its blurb text this idea of a 'rebirth' is somewhat qualified by the statement that 'the book does not aim to resurrect classical or Renaissance rhetoric, but to remake rhetoric within a contemporary context.'

I think that this very process of adaptation to the needs of the times has shaped the attitude toward rhetoric in all periods of history, dependent on the ongoing changes in government, politics, law, education, the production and reception of the arts – in brief, the changes in the overall social, ideological, and cultural situation. Surely, without this continuous practice of adjustment, classical rhetoric would have faded into oblivion a long time ago. Indeed, there is every reason to believe that the practice and theory of rhetoric-cum-style, in one form or another, will forever be a vital factor in human existence because, as said earlier, 'persuasion' is a cognitive and psychological symptom of human communication.

Style and Style Shifting

C Fought, Pitzer College, Claremont, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

From the very earliest sociolinguistic studies, it has been clear that style plays a crucial role in language variation. Fischer's seminal study (1958) of the-*ing*/-*in* alternation among schoolchildren in New England, for example, found that they used more of the lower-prestige variant, -*in*, in informal situations such as a conversation and progressively less of this variant in more formal situations, such as reciting a story in class. All of us have some intuitive sense of this in our own lives. We might feel comfortable using certain linguistic features at a dinner party with friends but will edit them out of our speech in a formal job interview.

But what is 'style' exactly? A number of theoretical approaches to explaining the role of style in sociolinguistics have been developed. One of the earliest, represented in Labov (1966, 1972), is the 'attention to speech' model. This approach views style as a function of the amount of consciousness individuals have of their speech in a particular setting. Labov (1966) studied a number of sociolinguistic variables in New York City and designed his interviews to encompass different types of contexts, including conversation, reading of a passage, and reading lists of words that included the relevant variables. He theorized that when speakers were more consciously aware of their speech, as when reading the word lists, they would use more of the prestige variants (e.g., the rhotic pronunciation for postvocalic -r). When they were more relaxed, in 'casual' speech (as identified by the nature of the topic by or certain paralinguistic cues, such as laughter or increased tempo), they would tend to use more lower-prestige variants. The results of Labov's study supported this hypothesis.

Other observations about style came out of this early work. The first was that the effects of style on variation tended to parallel the effects of social class. A variant that occurred more in informal styles also occurred more in the speech of individuals from the lower or working classes. Several researchers (Bell, 1984; Preston, 1991) subsequently pointed out that the amount of variation that corresponds to social factors is larger than that associated with stylistic factors. Another important observation was that of all the styles, the most 'casual' was also the most regular and the least subject to hypercorrections and other phenomena that tended to occur in the most formal styles. This finding led later researchers to focus on capturing the vernacular style as much as possible in their interviews.

Despite the importance of these early observations, the attention to speech model drew a certain amount of criticism. In particular, the unidimensionality of this model is problematic. The model assumes that attention to speech and formality covary with each other and with an increase in use of more prestige variants. However, Wolfram and Schilling-Estes (1998) identified a style that they labeled 'performance speech.' This style is exemplified by the Ocracoke Island, North Carolina, residents they studied, some of whom 'put on' a strong local dialect (unlike their natural conversational style) for tourists as a kind of performance. In these cases we find a style that involves a higher degree of attention to speech, but also a higher occurrence of the less prestigious or less formal linguistic variants associated with the local dialect. Another problem is the difficulty of measuring how much attention is being paid to speech, a factor that was often taken to be self-evident in the early studies or was measured with paralinguistic cues whose significance is ambiguous, such as laughter.

But what is 'style' exactly? A number of theoretical approaches to explaining the role of style in sociolinguistics have been developed. One of the earliest, represented in Labov (1966, 1972), is the 'attention to speech' model. This approach views style as a function of the amount of consciousness individuals have of their speech in a particular setting. Labov (1966) studied a number of sociolinguistic variables in New York City and designed his interviews to encompass different types of contexts, including conversation, reading of a passage, and reading lists of words that included the relevant variables. He theorized that when speakers were more consciously aware of their speech, as when reading the word lists, they would use more of the prestige variants (e.g., the rhotic pronunciation for postvocalic -r). When they were more relaxed, in 'casual' speech (as identified by the nature of the topic by or certain paralinguistic cues, such as laughter or increased tempo), they would tend to use more lower-prestige variants. The results of Labov's study supported this hypothesis.

Other observations about style came out of this early work. The first was that the effects of style on variation tended to parallel the effects of social class. A variant that occurred more in informal styles also occurred more in the speech of individuals from the lower or working classes. Several researchers (Bell, 1984; Preston, 1991) subsequently pointed out that the amount of variation that corresponds to social factors is larger than that associated with stylistic factors. Another important observation was that of all the styles, the most 'casual' was also the most regular and the least subject to hypercorrections and other phenomena that tended to occur in the most formal styles. This finding led later researchers to focus on capturing the vernacular style as much as possible in their interviews.

Despite the importance of these early observations, the attention to speech model drew a certain amount of criticism. In particular, the unidimensionality of this model is problematic. The model assumes that attention to speech and formality covary with each other and with an increase in use of more prestige variants. However, Wolfram and Schilling-Estes (1998) identified a style that they labeled 'performance speech.' This style is exemplified by the Ocracoke Island, North Carolina, residents they studied, some of whom 'put on' a strong local dialect (unlike their natural conversational style) for tourists as a kind of performance. In these cases we find a style that involves a higher degree of attention to speech, but also a higher occurrence of the less prestigious or less formal linguistic variants associated with the local dialect. Another problem is the difficulty of measuring how much attention is being paid to speech, a factor that was often taken to be self-evident in the early studies or was measured with paralinguistic cues whose significance is ambiguous, such as laughter.

Subsequent models have attempted to address these shortcomings and to provide a more complete account of style shifting. One of these is the 'speech accommodation' model (Giles and Powesland, 1975; Giles, 1984; Giles, Coupland, and Coupland, 1991). Originally developed by social psychologists, this approach focuses primarily on the social context, on what is going on outside the speaker. The central issue in determining style is not how much attention the speaker is paying to his or her own speech but rather the speaker's relationship to the other interactants in the speech event. Specifically, Giles and his colleagues' studies showed that individuals tend to converge with the speech of the person they are addressing, particularly when they want to position themselves as socially acceptable to their addressee. In other cases, individuals might diverge from the speech of the addressee in order to highlight a separate identity. The speech accommodation model addresses some of the concerns raised by the attention to speech model, but it is somewhat unidimensional in its focus on the addressee.

A similar but more elaborate model is the 'audience design' model, first proposed by Bell (1984). Bell's model also relies on a social frame of reference in which the relationships between the participants are given primary importance. However, he expanded the notion of the addressee to include others who might be listening to the conversation or even generalized others who are not present (termed 'referees'), such as a type of person with whom the speaker wishes to be identified. In this way the model is able to account for style shifts triggered by topic changes, for example. Certain topics may be associated with a well-educated, middle-class audience, while more informal ones may be associated with a peer group that speaks more in the vernacular. Overall, however, the emphasis is on convergence with (or divergence from) the specific addressee or audience present in the interaction. In a later study by Bell (2001), an unusual research design was used in which the gender and ethnic identities of the interviewer and interviewee were manipulated to test the process of accommodation. The study supported the predictions of the audience design model: the sociolinguistic features used were sensitive to the gender and ethnicity of the addressee, in addition to other factors.

A number of other important studies begin from similar perspectives but expand the early theories in some way. Coupland (1980) focused on the speaker's 'presentation of self,' integrating concepts from theories of sociology. In contrast with some of the other early studies, he placed greater emphasis on the functions of stylistic shifts, particularly the strategic use of stylistic variables in discourse. Coupland's presentation foreshadowed some recent approaches focusing on the construction of identity (see discussion below). Finegan and Biber (1994) attempted to explain the specific associations of particular linguistic variables with shifts in the situational context. In particular, they argued that communicative situations contain inherent register variations and posit that more "elaborated" linguistic variables (such as relative clauses) are associated with more literate or decontextualized settings and registers. In this way, they tie together the socioeconomic, stylistic, and linguistic correlates of language variation. In making the claim for a linear relationship between elaboration in linguistic structures, higher socioeconomic status, and formality, however, the Finegan and Biber model is subject to some of the same criticisms that were voiced about the attention to speech model. Their model, for instance, cannot account for situations in which the style relationships are more complex, such as certain types of performances that highlight vernacular features. Milroy (2001) noted some additional problems with the model, including issues over which features constitute elaboration and the difficulty of delimiting terms central to the model, such as 'ease' and 'clarity.'

Subsequent work on style in sociolinguistics sought to integrate style into models that view variation in language as part of the complex linguistic practices through which speakers construct their social identity. Rickford and McNair-Knox conducted a seminal study (1994) on the stylistic shifts by one African-American teenager (Foxy) in California. The researchers found that Foxy clearly shifted style on a number of African-American Vernacular English (AAVE) features in relationship to the race and familiarity of the interviewer and secondarily in response to certain topic shifts. Even though Rickford and McNair-Knox's study is often cited as providing evidence for the audience design model, it also highlights the importance of individual speakers' ways of using language to construct their identities in different contexts, rather than focusing on an entire community's style patterns, as the earliest studies did. The authors discussed at length an earlier interview in which Foxy used fewer AAVE features with the same African-American interviewer who conducted the later interviews. Although this interview initially seems anomalous in terms of Foxy's overall style pattern, the authors showed that in the context of Foxy's individual history, the pattern is explainable. Among other things, Foxy had just completed her first year at a predominantly white high school. Rickford and McNair-Knox argued convincingly for the view of style as "a resource . . ., an interactive and dynamic process" (1994: 264) in which we see a confluence of numerous contextual and interpersonal factors.

Eckert and Rickford (2001) have provided a crucial perspective on style in sociolinguistics, with chapters and critiques by many of the main researchers in this field. This collection encompasses both the history of discussions about style and some predictions for this area of research in the future. Several chapters attempt to define or redefine the primary terms in the discussion of style. Irvine's chapter, for instance, distinguishes register, dialect, and style, with style as the superordinate category for register, which tends to be associated with more established (often specifically labeled) situations. Macaulay provides a discussion of genre, another term used frequently in the literature on style but often not well defined. Yaeger-Dror's chapter explores a number of different terms and concepts in an attempt to delimit some of the 'primitives' of the analysis of style.

In terms of theoretical perspectives, a number of chapters in this collection illustrate the social constructionist approach mentioned earlier. Eckert's chapter, for instance, critiques the attention to speech model, emphasizing the need to locate style within the practices that make up an individual's personal and social identity. In particular, it discusses how the linguistic and other behaviors of particular small cohorts or individuals within a larger social group become salient; these behaviors then provide a window for observing the process by which particular linguistic variables acquire social meaning. Ervin-Tripp's contribution provides an analysis of the rhetorical style of two African-American political leaders, showing how the strategic use of AAVE features reveals complicated manipulations of the established language ideologies for particular effects. Coupland studied a Cardiff DJ and the complex social and attitudinal dynamics evoked by his use of standard/nonstandard and local/nonlocal features. Coupland concluded that speakers are putting together a complex linguistic performance rather than simply responding to specific factors in the situation. Rickford, however, cautions sociolinguists against completely discarding analyses of larger social groups and their styles in favor of a focus solely on the individual and argues for using multiple approaches simultaneously. Eckert and Rickford offer this conclusion about style in their introduction: "As we move toward viewing social life as a continual process of constructing ... categories and identities, style becomes in addition a resource for the process of construction" (2001: 6).

Stylistics

K Wales, University of Leeds, Leeds, UK

Definition and Domain

Stylistics is broadly and simply 'the study of style,' a concept that is widely known and used, but that is difficult to define and has many different shadings. What is certain, however, is that its essence is 'distinction,' 'variation,' or 'choice': in any language there is always more than one way of writing or speaking the same (sic) message, but with a different connotation or effect as a result. Stylistics as a discipline takes as its base this essential variation, whether at the level of phonology, grammar, lexis, semantics, or discourse. It differs from sociolinguistics, where style is seen as a variable within a continuously evolving sociolinguistic system, in being concerned with the functional significance of style. It characteristically deals with the interpretation of texts by focusing in detail on relevant distinctive linguistic features, patterns, structures, or levels and on their significance and effects on readers. It presupposes that every linguistic feature in a text has potential significance. It draws its terminology and models from various appropriate branches of linguistics, and one of the commonest collocations and metaphors associated with it is 'toolbox' or 'tool kit.' Since attention is predominantly text centered, stylistics could arguably be a branch of text linguistics; and since it uses linguistic frameworks, it could also be seen as a branch of applied linguistics. It is sometimes also called *literary stylistics or literary linguistics* (see, e.g., Fabb, 1997; Stockwell, 2000) because the most common kinds of texts traditionally analyzed have been literary. It could also be regarded as a branch of poetics, which is primarily concerned with the classification of the essential properties or conventions of genres, or theories of form. There is some overlap in usage, however, and in territory: there are stylistic studies of satire, parody, and humor, for instance.

Nonliterary discourse and varieties or registers are well within the scope of general stylistics or sociostylistics, and spoken as well as written; increasingly attention is being drawn cross-modally to media discourses such as those of film, news reporting, advertising, politics, and hypertexts and to the oral discourses of storytelling and song lyric. The term *linguistic stylistics* is sometimes found, which acknowledges the fact that some stylistic studies are as interested in providing insights into the workings of language and in testing the validity of linguistic models as they are in providing insights into how texts mean. However, it has to be said that a stylistic study of any merit will say as much about (the limitations of) the model as about the text under scrutiny.

Roger Fowler's term for stylistics was *linguistic criticism* (1986), reflecting not only the fact that primacy is assigned to language, but also that the goal of stylistic studies is not simply a mechanistic description of the formal features of texts for their own sake, whether phonological, grammatical, or lexical – a common myth about the early years of stylistics in Britain in the 1960s. Linguistic analysis, however objective or empirical, is no substitute for deductions and judgments. The aim is to find linguistic evidence for a critical judgment; to ground intuitions or hypotheses in a rigorous, methodical, and explicit textual basis; to produce an analysis that is verifiable. Fowler's term, *linguistic criticism,* also implicates stylistics with literary criticism and practical criticism, with their own focus on relating analysis to textual interpretation, but usually more broadly. A related term to Fowler's is *practical stylistics* (see Widdowson, 1992). Both literary criticism and stylistics can thus be seen as subdisciplines of hermeneutics, but stylistics is as much focused on *how* texts mean, as on *what* they mean, even though the goal may well be a specific literary-critical reading. Unlike literary critics, however, stylisticians must be concerned with language, and stylistics provides a metalanguage for principled and systematic discussion of it, in its concern also to avoid subjective or impressionistic judgments based on unverifiable intuitions. Not that good literary criticism is vague or impressionistic.

Stylistics in Britain at least has tended to fight shy of evaluation, of what is good or bad style, possibly as a reaction against the prescriptivist Leavisite tradition of literary criticism and notions of the canon. Assessments are indeed made, but of the effectiveness or appropriateness of specific stylistic features to their perceived function or contribution to the totality of interpretation. Stylisticians have to be wary, however, of making oversimplistic iconic equations between language forms and functions or meanings (the so-called enactment fallacy), despite the characteristic symbiosis in poetry in particular between form and meaning. For, as Simpson rightly argues (2004: 2), linguistic features 'do not of themselves constitute a text's meaning', but act as a 'gateway' to its interpretation. It therefore follows that more than one interpretation is possible. In recent years it has certainly been the case that stylistics has developed a harder edge and engaged in critique. For example, many stylistic studies draw their frames of reference from

critical theory (e.g., postcolonialism and the writings of Foucault on *discourse*) and feminist stylistics is an important subbranch (see Mills, 1995). This has exposed areas of bias, inequality, and subjectivity where ethical issues can be raised. Very significantly, as a result of Roger Fowler's interest from the 1980s onward in critical linguistics, stylistics began to place emphasis on language and texts located and functioning in particular social, ideological, and political practices and has exposed linguistic ambiguity and obfuscation. So it has come increasingly to overlap with the Faircloughian critical discourse analysis (CDA), by which it has also been much influenced. But stylistics has always stressed the inseparability of form and content, which underpins the CDA approach, and the impossibility of a neutral or unmarked style. Deidre Burton's piece (1982) on the grammatical choices in Sylvia Plath's *The Bell Jar* could indeed be seen as a forerunner of CDA, in its argument for a radical stylistics that actually effects social change. In turn, CDA tends to use the 'tool kit' approach of stylistics as part of its methodology.

Stylistics in Academia

Because of its interface with many other different kinds of disciplines, stylistics tends to find itself both marginalized and appropriated at both one and the same time in higher education in the United Kingdom. Stylisticians have tended to find themselves caught between a literature and linguistic divide that has been slow in narrowing. At the end of the 1970s the Poetics and Linguistics Association (PALA) was founded by a group of like-minded scholars (including Ronald Carter, Roger Fowler, Mick Short, and Katie Wales) to provide a common forum and to legitimize stylistics as a professional discipline. The name of the association was chosen to reflect Roman Jakobson's famous statement that "a linguist deaf to the poetic functions of language and a literary scholar indifferent to linguistics are equally flagrant anachronisms." By the end of the 20th century, PALA had grown worldwide, with an annual conference and its own international journal, *Language and Literature*, which produces an annual resume of the year's work in stylistics.

As a branch of applied linguistics, stylistics even today may or may not be studied in the United Kingdom as part of a linguistics degree; with an emphasis on literature, it may or may not be part of an English or modern languages degree, although increasingly it features as a component of courses introducing students to critical theories and practices for text analysis and most recently as a component of creative writing courses. In the future this will undoubtedly mean that more attention will be paid to the pragmatic evaluation of style and the rhetoric of composition. Stylistics is increasingly studied as part of an English language degree, because of its popularity with English-speaking linguists researching aspects of English language, both synchronically and diachronically. English language degrees are themselves now flourishing as a result of the increased attention paid to English language studies in the last decades of the 20th century at the advanced level, and stylistics has accordingly found itself a receptive audience among secondary-level teachers and students of both language and literature.

The attraction of stylistics in the pedagogic context, namely that it combines a knowledge of the principles of language and usage with a critical interest in the interpretation of texts, has long been known outside the United Kingdom, in institutions and courses from Europe to Japan (e.g., those run by the British Council) where the language and literature of second languages, English in particular, are taught. The argument of those involved in pedagogical stylistics is that it enables students to be more aware of, and to be more explicit about, language features and use and at all levels of phonology, graphology, grammar, lexis, meaning, and discourse by providing them with an appropriate framework and vocabulary: the 'tool-kit.' It also helps students to be more independent in their judgments, by forming their own interpretations of literary texts based on close readings and to be more confident in articulating them. Some teachers believe that stylistics helps students to improve their own writing skills, as well as their reading skills, but empirical evidence for this is hard to find. The stylistics approach has always been very accessible, practical, and interactive, and publications in this area have focused on teaching materials (see, e.g., McRae, 1998; Widdowson, 1992). Rewriting exercises of the kind practiced in pedagogical stylistics (e.g., from prose to verse, changing perspective or focalization) have refreshingly found their way into United Kingdom textbooks like Rob Pope's (1995). With the increasing interest in English in China in recent decades, stylistics has become a major discipline; here as elsewhere, it has proved a staple of translation studies in both ancient and modern languages as well as English (see further Shen, 1995).

A Brief History of Stylistics

Already it can be seen that stylistics continually overspreads any firm discipline boundary because of its

engagement with other related disciplines across the arts, humanities, and even social sciences. Historically this has resulted in what can be termed a paradigm shift, although many concepts and strategies remain central or are continually being reassessed or even revived.

It is difficult to pinpoint the exact beginning of stylistics, because of its probable multinational origins at different times. One major root lies in the earlier study of *elocutio* in Western and European rhetoric, concerned with stylistic devices and patterned language such as schemes and tropes, which still plays a significant part in the teaching of composition in higher education in the United States. Other aspects of rhetoric remain of significance (e.g., its concern with the skills of public speaking as a means of persuasion, as having an effect on the audience). A general interest in rhetoric has recently been revived from a cognitive stylistics perspective (see further later discussion). The term *stylistique* was introduced by Charles Bally (1909), a pupil of Ferdinand de Saussure, and interest spread across Europe aided by the work of Leo Spitzer in particular (1928, 1948). Spitzer's interest tended to be writer centered: style seen as revealing the soul of the writer, and with an aim to find the creative principle of the text (expressive stylistics). His concept of the *philological circle* has been more enduring and is characteristic of the stylistician's procedure still today: constantly and delicately moving between hypothesis, linguistic analysis of data, and critical explanation and aesthetic response, with a revised hypothesis if necessary. Later continental stylistics in France aligned itself with semiotics, narratology, and philosophy; in Germany it acquired a diachronic and nonliterary emphasis. (For useful summaries of preoccupations in present-day *Stilistik* in Germany, see Sowinski, 1999; for *la stylistique* in France, see Molinié, 1997.)

In the 1960s stylistics took hold in Britain and the United States, given impetus from developments in descriptive linguistics, particularly grammar. The United States led the way in international journals of stylistics, notably *Language and Style* and *Style*. Michael Halliday proved a key figure in Britain (and subsequently Australia), first of all with his scale and category grammar, and also his concept of register as a situational use of language. But it is his later systemic-functional model of grammar that persistently provides one of the most popular tools in stylistic analysis, because of its comprehensive set of lexico-grammatical categories that label mental processes, verbal and material actions and so are able to tackle full-length naturalistic texts more easily than a generative grammar. His idea of *transitivity* in particular also underpins many writings in feminist stylistics and CDA.

Early stylistic studies of the 1960s in Britain and the United States were much influenced by the newly discovered early 20th-century works of the Russian Formalists, the Prague School, and the writings on poetic language and meter by Roman Jakobson; and terms like *parallelism, norm, deviation,* and *foregrounding* entered the stylisticians' vocabulary (see van Peer, 1986 for the latter): concepts and terms recently revived with a cognitive slant by Cook (1994). Leech (1969) happily blended Formalism and *elocutio* in his schematic reassessment of patterned language and metaphor in poetry. There was certainly a tendency in the early days of stylistics, later corrected, to study poetic texts, particularly those showing a high degree of linguistic creativity or experimentation. Jakobson's notion of literariness was much debated and still is, although stylisticians today tend to agree with literary critics in seeing a continuum of literariness in language across nonliterary as well as literary discourses (whether high or noncanonical). They tend to argue also that cultural expectations about what makes a text literary are as highly significant as prototypical linguistic, metrical, and textual features. Nonetheless, there are those who would argue, in line with Jakobson's emphasis, that literary texts have a different social function from nonliterary texts (see Widdowson, 1975, 1992; Verdonk, 2002); and it is certainly the case that aesthetic uses of language remain of central interest in stylistics, and studies of poetic form and prosody provide a flourishing subbranch of the discipline.

At around the same time there was also a brief flirtation with generative grammar as a model, because of its then interest, for example, in deviation, by the violation of selection rules or by degrees of grammaticalness, particularly in modern poetic texts such as those by e. e. cummings. The inheritance of generative grammar, however, as indeed of Formalism, proved more robust in generative metrics and in later evolved studies of metrical form (see, e.g., Fabb, 1997).

From the outset in Britain stylistics tended not to be writer centered. Although concerned with the concept of *narrator,* it showed little interest in authorial intention, as in traditional literary criticism. Periodically, however, there has been interest in stylistic features that mark an author's *idiolect* or voice print across an oeuvre or in changes of style between early and later works or that indicate provenance, especially in computational stylistics and forensic stylistics, where cases of disputed authorship arise. There has also been an implicit awareness that any choice or selection of stylistic features must have been

the author's. The concern in the 1960s and early 1970s was very much with the reification of the text as an artifact (formalist stylistics). One inheritance of this is the implicit assumption that the text under scrutiny is coherent and cohesive.

However, with the development in the 1970s of disciplines such as discourse analysis and pragmatics in linguistics on the one hand and reception aesthetics and reader-response criticism in literary theory on the other, stylistics shifted its focus to the text in its interactive discourse context (functional stylistics, discourse stylistics, or contextualized stylistics) and to the reader as constructing the meaning of the text, rather than as simply the decoder of a given message or single or eternal truth encoded by the writer. There was a more explicit recognition that the parameters of the situational context contributed to a text's meaning, and that therefore contextualization needs to be part of the theory or model. The writings of the Russian linguist philosopher Mikhail Bakhtin, newly discovered and translated in the West, gave a refreshing boost in the 1980s to the study of the style and structure of prose fiction in a sociostylistic context and introduced the notion of *intertextuality*, texts and their voices in a creative dialogue with others. Prose fiction inevitably lent itself to macrodiscoursal approaches, such as *focalization* or *point of view* and *speech and thought presentation* (see Leech and Short, 1981), which continue today, aided by the advent of corpora for empirical testing and verification. However, stylisticians are still firmly committed to linking macrostructures to the micro, specific linguistic features themselves. Burton (1980) led the way in the stylistic analysis of drama by applying a comprehensive discourse model matching fictive dialogues against real-life conversational practices. This was later followed in many studies by the application of pragmatic models of politeness and speech act theory. Herman (1995) remains the most comprehensive analysis of drama from different perspectives, recognizing that drama's discourse context is characteristically complex.

Certainly, in general, the awareness of context meant that a diachronic stylistics could valuably develop, matching trends in pragmatics, with a sensitivity to nuances of style and significance in texts grounded in a sociohistorical, rather than simply in an ahistorical context; and taking into account differences of reader or audience expectations from earlier periods (see, e.g., Adamson, 2000). A diachronic stylistics also looks at the historical development of significant stylistic devices, such as free indirect speech and thought. The increasing awareness in pragmatics also of the need to embrace a cross-cultural perspective, for example in politeness theory, is influencing many studies in contrastive rhetoric, especially those embedded in English as a Foreign Language pedagogy and also drawing inspiration from the field of genre analysis.

Current Trends in Stylistics—and the Future?

Stylistics today is still broadly concerned with the creative negotiation of meaning and affect between texts, contexts, and readers, and this emphasis has been reinforced by developments not only in pragmatics, but also in cognitive linguistics. The 1990s saw an emerging interest in the application of relevance theory (relevance stylistics): phenomena such as poetic metaphors leading to extra interpretive effort on the part of the reader. In what is called cognitive stylistics, or cognitive poetics more generally, there is a strong interest in the actual reading **process** (rather than the end **product**) and how specific linguistic features or textual elements trigger a reader's understanding and the mental creation of the world of the text, especially in fiction (see Emmott, 1997; Werth, 1999); also in the understanding and processing of metaphors and the manipulation of prior mental schemas and frames of knowledge (see Semino and Culpeper, 2002). As with other strands of stylistics, the most interesting research tests the strength of the cognitive models much as illuminating the text under discussion. Cognitive linguistics in general breaks down the traditional binary opposition between *literal* and *figurative* meaning, which is appealing to stylisticians. In its history it has contested many such oppositions, inherited from the worldview of a Saussurian structuralism (e.g., *text* vs. *context*; *literary* vs. *nonliterary*; *mimesis* vs. *diegesis*).

Although a focus on process is to be welcomed, for the future, however, stylistics must continue to concern itself as much with the social, cultural, and historical contexts as the cognitive and take more notice of global discourse communities, rather than Anglocentric, in which texts are constructed and construed, and to the diverse nature of real readers and reading publics. Recent work at the University of Nottingham on spoken corpora under the direction of Ronald Carter has highlighted the creativity of ordinary speech, but there is also still a great need for the stylistic analysis of computer-enhanced large-scale corpora of a range of text and discourse types and from different periods and also for a stylistic perspective on lexical phenomena such as collocations and formulas in such corpora: all under the heading of a corpus stylistics. The new aesthetic multimodal genres of video games and Internet literature

also await more attention. Literary theorists have long prophesied the replacement of the study of literature by cultural studies. Stylistics is well placed to move into the analysis of forms of cultural production other than written texts.

Conclusion

As this account of stylistics illustrates, Lecercle (1993) is right to state, on the one hand, that no one has probably ever known exactly what the term *stylistics* comprises, yet, on the other hand, that the discipline is forever being reborn. Those engaged in stylistics see this as a strength, as in other disciplines that continually reassess their models and theories, and they embrace its eclecticism with zeal. That there is no one way to do stylistics might be disconcerting to some. However, stylistics is no different from many other disciplines at the present day in that there is continual cross-fertilization of ideas across subject boundaries and the stretching of its own boundaries at the same time. And although models may change or vary, the fact remains that those stylistic studies that are the most illuminating provide scrupulous insights into both the workings of language and the interpretations of texts that remain plausible and convincing to new generations of readers.

Cognitive stylistics is a relatively new, rapidly developing field of language study that attempts to describe and account for what happens in the minds of readers when they interface with (literary) language. It focuses on a variety of texts, both persuasive and rhetorical, that appear in all kinds of social domains. It is, however, most readily and most often applied to the analysis of literary texts, ranging from the popular to the canonical. Cognitive stylistics is thus crucially concerned with reading, and, more specifically, with the reception and subsequent interpretation processes that are both active and activated during reading procedures. Hence, at its core, cognitive stylistics sets out to answer two main questions: first, what do people do when they read? And second, what happens to readers when they read? Implicit in these questions is the role that unconscious and conscious cognitive and emotive processes play when an individual or group of individuals interface with a linguistic text that has been purposely designed with the aim of eliciting certain emotions in a reader.

The Evolution of the Field

Cognitive stylistics can be said to have evolved primarily from literary stylistics, a field also known as literary linguistics. Literary stylistics is the systematic study of (literary) language and (literary) style. Its roots are located in the classical rhetorical and poetic work of Aristotle. Modern literary stylistics, however, as practised in the late 20th century, took many of its cues from the Jakobson-inspired work of the early-20th-century Russian Formalists and Czech Structuralists. For much of that century, stylistics was primarily a formal affair, with text and language playing a dominant role. Slowly but surely, however, readers and their contexts began to play an equally important role in interpretation and meaning-making. The notion of 'context,' still crucial in current cognitive stylistics, refers not just to the sociocultural context of a reading situation, i.e., questions pertaining to who speaks, to whom, where, and so on, but also to an emotive-cognitive context. Contextual developments in linguistics on the one hand, in the form of functional and cognitive approaches to language study, and the somewhat similar contextual developments in literary studies on the other hand, in the form of reading reception and phenomenology, heralded a parallel need in stylistic scholarship for a rigorous and replicable account to be given for the mental processes, as well as the already existing linguistic ones, that come into play during reading.

The main difference between mainstream literary stylistics and cognitive stylistics is that whereas the former focuses almost exclusively on language, style, and other formal linguistic aspects of processing, the latter expands on these 'bottom-up' processing features, and also considers the cognitive, affective, and mnemonic aspects of 'top-down' processing. This addition is something that literary stylistics had not previously dealt with in any systematic or meaningful way. In hindsight therefore, it can indeed be said that literary stylistics, with its bottom-up input, was crucial to the way cognitive stylistics developed, and indeed to how it is still developing today. The field of cognitive stylistics has also been influenced by other academic disciplines, some outside the humanities. The most relevant of these are cognitive psychology, discourse psychology, and, most prominently, cognitive linguistics.

Cognitive stylistics builds on the linguistic-analytic rigour of literary stylistics by attempting to account for and describe the cognitive and mental processes that underpin and channel aspects of meaning-making. This is especially the case in the reception of written (literary) language. As Semino and Culpeper put it, "cognitive stylistics is the way in which linguistic analysis is systematically based on theories that relate linguistic choices to cognitive structures and processes" (2002: ix). In effect, therefore, cognitive stylistics is centrally concerned with trying to describe, define, and account for the role of cognition and emotion in reading procedures. In this sense it can be seen as a kind of discourse psychology for the humanities: a search for the cognitive and emotive sources of aesthetic persuasion for inter-subjective ends, rather than exclusively for sociological ones.

Cognitive stylistics, however, when conducted properly, does not treat literary texts as mere linguistic data. Rather, sensitive cognitive stylisticians will at all times be aware and mindful of the aesthetic nature of the text they are analyzing. This sensitivity, required for any interpretative-analytic approach to a work of art, including literature, must also attempt to manifest itself in the above mentioned 'inter-subjective' interpretations that span the meaning-making realties of the individual reader and like-minded groups of readers. At no time, therefore, can one speak merely of 'readers' or 'a' reading, despite the physiological, and oftentimes cultural, similarities that can sometimes exist between readers or reading communities. Hence, in cognitive stylistics, reading processes are

neither wholly subjective nor wholly objective, but are instead inter-subjective and, as such, are dynamic and context-determined.

The term 'cognitive stylistics' is also used interchangeably, and oftentimes somewhat confusingly, with the term 'cognitive poetics.' An ongoing debate between the key scholars in the field finds the stylistics group drawing on cognitive and discourse psychology, while the poetics group relies on the work of American West-coast cognitive linguists (e.g., Lakoff and Johnson, 1980, 1999; Lakoff and Turner, 1989; Turner, 1991, 1996; and Fauconnier and Turner, 2003). Despite there being some truth in the claim that cognitive approaches to stylistics and poetics are dissimilar, this difference is far more theoretical than it is factual. In practice, there is no substantial divide between the work currently being conducted under these two labels. This can be seen in a number of ways, one of which is the fact that cognitive linguistics is itself, to a large extent, grounded in the work of cognitive psychology. An example of this is Rosch's (1978) work on prototypes and categories, which formed the base for similar work conducted later in cognitive linguistics, which subsequently fed into cognitive stylistics. Similarly, one can also point to the much earlier Gestalt psychological roots of the 'figure and ground' analysis which has informed and shaped certain aspects of cognitive linguistics, especially cognitive grammar.

The division between cognitive poetic and cognitive stylistic approaches has fueled discussion as to which term best serves to describe the field. The latter has several advantages. The term 'stylistics' focuses on the importance of the crucial bottom-up aspects of style in meaning-making, which can get lost in the study of language once the term 'cognitive' has entered into the equation. The use of the term 'stylistics' therefore reflects the constant need to pay attention to the **interaction** between bottom-up and top-down processes in reading procedures and not to lose sight of the textual input completely. The term 'cognitive stylistics' strikes an optimum balance, since the word 'cognitive' covers the top-down aspects of processing, while the word 'stylistics' covers the bottom-up aspects. The result of this is a focus on that which truly matters, namely, attempting to observe, describe, and define the relationship and the interaction between the two processes in diverse single and multiple reading contexts.

By comparison, the term 'poetics' does not adequately capture or represent the formal nature of language and style that must be addressed in any analysis employing linguistic/stylistic criticism, be it feminist, pragmatic, pedagogical, computational, corpus, historical or, as in this case, cognitive. Furthermore, the term 'cognitive poetics' is already in use to describe Reuven Tsur's work, which tends to focus much more on the perceived effects observed in texts by readers (1992). A further distinction in Tsur's work is that it is centrally concerned with how poems and literary texts might convey emotions through a variety of mechanisms, including, for example, rhythm and meter (1998). Perhaps the greatest difference, however, is that whereas cognitive stylistics by and large tries to identify similarities in the effects and processes that a certain group of readers might undergo, Tsur's cognitive poetics attempts to focus on aspects of individuality, uniqueness, and creativity in reception processes. This he often does by including a quantitative empirical approach to the study of literature, something that many cognitive stylisticians currently do less frequently.

Literature

Despite the relative newness of the discipline, a number of engaging and interesting books have already been written. These include Stockwell's (2002) monographic work, which describes and applies a number of cognitive stylistic tools to a large number of literary texts, and also the edited volumes by Semino and Culpeper (2002) and Gavins and Steen (2003), the latter of which is a companion volume to Stockwell's work.

In these works, and in a number of journal articles, scholars draw on different sources to produce cognitive stylistic analytic frameworks. These include ideas from (1) cognitive linguistics, (2) text and narrative theories, and (3) artificial intelligence. The first of these includes cognitive stylistic analyses of cognitive metaphor (Crisp, 2003; Freeman, 1993, 1995); cognitive parable (Burke, 2003); cognitive grammar (Hamilton, 2003); mental spaces (Semino, 2003); figures and grounds (Stockwell, 2003); and prototypes (Gibbs, 2003).

The second group, text and narrative-based analysis, includes cognitive stylistic work on plot reversals in narrative texts (Emmott, 2003), which in turn is grounded in Emmott's earlier (1997) monographic work. Drawing on insights from discourse analysis and artificial intelligence, this work considers how readers construct and maintain mental representations of fictional characters and contexts. A further example in this category is Gavins's (2003) examination of difficult and bizarre reading conditions within a text world theory framework. Gavins's main theoretical framework relies on Werth's (1999) monographic work on text world theory which, taking into account both bottom-up and top-down processes in fiction and nonfiction reading, seeks to provide a

replicable framework where entire discourses can be systematically analyzed. Such discourse-based approaches, which attempt to look at whole texts instead of just text fragments, as the cognitive linguistic group often does, have been influenced by studies in both narrative discourse and discourse psychology.

Third are cognitive stylistic studies that have taken their cue from artificial intelligence. The majority of these find form in schema theory analyses. Some influential studies include Verdonk's (1999) work on Larkin's poetry and Cockcroft's (2004) work on rhetoric (which mainly focuses on Aristotle's ethos, pathos, and logos). In addition to these articles, two monographs, one by Cook (1994) and one by Semino (1997), devote much attention to schema theory analyses of poetry.

Conclusion

The field of cognitive stylistics is still very much in its formative years. What happens in the brain, mind, and body of a reading individual when he or she interfaces with a text, and especially a literary text that has been designed thematically and stylistically to produce emotion in the reader, is not a question that will be answered either quickly or easily. Theoretical advances in cognitive linguistics, cognitive psychology, and discourse psychology, as well as in artificial intelligence and neuroscience, will undoubtedly drip-feed into the field of cognitive stylistics as it develops, thus helping to illuminate the interactive roles that bottom-up and top-down processes play in a variety of subjective and inter-subjective literary discourse processing situations.

Where literary stylistics is concerned with language and literary studies, cognitive stylistics has added a third and crucial psychological dimension to this binary matrix, namely the field of cognitive neuroscience. For all intents and purposes therefore, cognitive stylistics is, by its very nature, working toward the development of a cognitive – and plausibly, in time, even neural – theory of (literary) reading processes. This necessary and predictable inclusion of a cognitive and emotive dimension, given the direction of current studies in psychology and linguistics, makes cognitive stylistics a worthy, and indeed a quite logical, descendant of literary stylistics.

Stylistics, Feminist

S Mills, Sheffield Hallam University, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Feminist stylistics is concerned with the analysis of the way that questions of gender impact on the production and interpretation of texts. However, in order to do this type of analysis it is not enough to consider solely the text itself and the type of language which is used. What has been termed second-wave feminist analysis (broadly speaking, the feminism of the 1960s and 1970s which concentrated on the analysis of sexism and the oppression of women) examined, for example, the way that female characters or male characters are represented, especially in relation to sexist stereotyping (Sunderland *et al*., 2002); the use of the so-called generic pronoun 'he' and the use of generic nouns especially in relation to sexism; and the use of derogatory lexis in relation to women in texts (Schultz, 1990). However, it has become clear that feminist stylistics needs to move beyond this type of textual analysis and examine beyond the phrase and sentence, in order to example discourse-level features, for example, the way that direct or indirect speech is used for male and female characters and the impact that this has on whose voice is believed in texts (Caldas-Coulthard, 1994); the way that particular collocations tend to occur when referring to women or men (Carroll and Kowitz, 1994); or the way that a text addresses its readership in gendered terms (Mills, 1994a). Furthermore, it is necessary to go beyond the text itself and examine the types of judgment which are made of female authors and their writing, and the impact that this has on whether their books remain in print. In all of these levels of analysis it is necessary to acknowledge that the meaning of individual items or even of wider discourse-level features cannot be assumed to be inherent to those particular elements themselves, but that they are subject to interpretation on the part of the reader. These interpretative processes are not simply within the control of individual readers but rely on a range of ideological information about gender which circulates within the wider society or within particular communities of practice (Eckert and McConnell-Ginet, 1998, 1999). Thus, rather than assuming that notions of gender are simply a question of discriminatory messages about sex difference embedded in texts, feminist stylistics is concerned with unraveling the complex messages which may be deduced from texts and also with analyzing the way that readers piece together or resist these messages. In addition, this new form of discourse-level feminist analysis, which is often termed third-wave feminism, is keenly aware that not all women (or men) are the same, and therefore it is necessary to analyze the social, across-the-board discriminations which seem to apply to women as a whole, but also to examine more local manifestations of stereotyping and resistances to such ideologies (Eckert and McConnell-Ginet, 2003).

Sexism has been a key concern of feminist linguists, but it has become more and more difficult to pin down what sexism consists of and to agree that certain words or phrases are unequivocally sexist (Dunant, 1994). While feminist linguists still concern themselves with the type of vocabulary which is used to describe female characters in texts, there is a sense in which they have moved to describe a wider range of features which contribute to certain messages being constructed about women. Furthermore, they have recognized that there are forms of indirect sexism which draw on irony and humor which are more difficult to identity than the direct sexism which was the focus of second-wave feminist analysis (Mills, 2002). Feminists have also moved stylistic analysis from the literary sphere to analyze a wider range of texts, for example, newspapers and advertisements. Kate Clark analyzed the types of language that are associated with the representations of women in tabloid newspaper in relation to sexual violence, which she asserts tend to blame the victim rather than the perpetrator (Clark, 1998). Instead of simply analyzing vocabulary, Clark analyzed the transitivity patterns (that is, who does what to whom) in these texts

Stylistics, Feminist

S Mills, Sheffield Hallam University, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Feminist stylistics is concerned with the analysis of the way that questions of gender impact on the production and interpretation of texts. However, in order to do this type of analysis it is not enough to consider solely the text itself and the type of language which is used. What has been termed second-wave feminist analysis (broadly speaking, the feminism of the 1960s and 1970s which concentrated on the analysis of sexism and the oppression of women) examined, for example, the way that female characters or male characters are represented, especially in relation to sexist stereotyping (Sunderland *et al*., 2002); the use of the so-called generic pronoun 'he' and the use of generic nouns especially in relation to sexism; and the use of derogatory lexis in relation to women in texts (Schultz, 1990). However, it has become clear that feminist stylistics needs to move beyond this type of textual analysis and examine beyond the phrase and sentence, in order to example discourse-level features, for example, the way that direct or indirect speech is used for male and female characters and the impact that this has on whose voice is believed in texts (Caldas-Coulthard, 1994); the way that particular collocations tend to occur when referring to women or men (Carroll and Kowitz, 1994); or the way that a text addresses its readership in gendered terms (Mills, 1994a). Furthermore, it is necessary to go beyond the text itself and examine the types of judgment which are made of female authors and their writing, and the impact that this has on whether their books remain in print. In all of these levels of analysis it is necessary to acknowledge that the meaning of individual items or even of wider discourse-level features cannot be assumed to be inherent to those particular elements themselves, but that they are subject to interpretation on the part of the reader. These interpretative processes are not simply within the control of individual readers but rely on a range of ideological information about gender which circulates within the wider society or within particular communities of practice (Eckert and McConnell-Ginet, 1998, 1999). Thus, rather than assuming that notions of gender are simply a question of discriminatory messages about sex difference embedded in texts, feminist stylistics is concerned with unraveling the complex messages which may be deduced from texts and also with analyzing the way that readers piece together or resist these messages. In addition, this new form of discourse-level feminist analysis, which is often termed third-wave feminism, is keenly aware that not all women (or men) are the same, and therefore it is necessary to analyze the social, across-the-board discriminations which seem to apply to women as a whole, but also to examine more local manifestations of stereotyping and resistances to such ideologies (Eckert and McConnell-Ginet, 2003).

Sexism has been a key concern of feminist linguists, but it has become more and more difficult to pin down what sexism consists of and to agree that certain words or phrases are unequivocally sexist (Dunant, 1994). While feminist linguists still concern themselves with the type of vocabulary which is used to describe female characters in texts, there is a sense in which they have moved to describe a wider range of features which contribute to certain messages being constructed about women. Furthermore, they have recognized that there are forms of indirect sexism which draw on irony and humor which are more difficult to identity than the direct sexism which was the focus of second-wave feminist analysis (Mills, 2002). Feminists have also moved stylistic analysis from the literary sphere to analyze a wider range of texts, for example, newspapers and advertisements. Kate Clark analyzed the types of language that are associated with the representations of women in tabloid newspaper in relation to sexual violence, which she asserts tend to blame the victim rather than the perpetrator (Clark, 1998). Instead of simply analyzing vocabulary, Clark analyzed the transitivity patterns (that is, who does what to whom) in these texts

and a range of other linguistic features in order to examine the complex process whereby blame is insinuated. Rather than assuming that particular vocabulary items contain sexist meaning, Carroll and Kowitz (1994) examined the process whereby meaning accrues to words which have gendered reference. They used a concordance of a text database and examined, for example, the way that the term 'woman' collocates (or keeps company) with words such as 'busy' and 'beautiful,' in contrast to the words which collocate with 'man' such as 'important' and 'rich.' They argue that these collocations give the words 'man' and 'woman' different values or associations which lead to their different ranges of connotative meaning. They also look at words including 'husband' and 'wife' and show that these two terms do not occur equally frequently in texts, with 'wife' occurring much more frequently. Thus, 'wife' is assumed to be a word that can occur in a possessive relation to other words (e.g., 'Mike's wife,' 'Mike and his wife'), whereas 'husband' does not occur in these positions as frequently. Thus, rather than assuming that any negative or derogatory meanings that occur in relation to women are contained within particular lexical items, they show that meanings accumulate from the type of 'company' a word keeps. If a term such as 'single-parent' is used in the context of children's problem behavior or in the context of poverty, then it will start to develop negative connotations. Here feminist stylistics examines discriminatory practices in texts, but is less interested in making stark clear-cut generalizations about vocabulary used for men and women; here analysis is focused on the complex process whereby certain words begin to develop negative connotations.

Transitivity has been analyzed by a number of feminist stylisticians, most notably by Deirdre Burton, in her analysis of Sylvia Plath's writing (Burton, 1982). Burton's work aimed to show that there are particular verbal choices which are, as she put it, 'disenabling' for women; that is, when women represent themselves as 'acted upon' by others, rather than 'acting' themselves, for example when authors use verbal choices such as 'he hit her' or 'she was hit by him' rather than 'she called the police.' By looking at the types of verbal choices made by female authors across large chunks of text, Burton is able to argue that the meaning of a text is constructed out of these repeated patterns. Wareing has taken this work further in her analysis of romantic novels, arguing that even when female characters act strongly, they are often acted upon in sexual scenes (Wareing, 1994). She therefore argued that we need to analyze the way that there may be a range of different transitivity choices within literary texts depending on the context.

Rather than simply analyzing the way the vocabulary items construct particular characters, some feminist linguists have argued that we need to analyze the point from which characters are viewed, since if characters are viewed negatively by the narrator, this will color the reader's judgment of them. Semino (2002) has analyzed the mind style of particular narratives and the way that this is constructed from a range of different linguistic elements. Other feminists have argued that we need to analyze how the text addresses the reader, either by direct address (addressing the reader as 'you') or by indirect address, for example, assuming that certain information can be considered to be common sense or shared (Mills, 1994a; Montgomery *et al.*, 2002). A dominant reading is one which the text constructs as the self-evident interpretation for the text, and this reading may be composed of ideological information. However, readers may find that they wish to construct a resisting reading of the text, informed perhaps by feminist thought (Fetterley, 1978). The interpretation that we construct of a text will therefore be a complex negotiation between reader and text with neither of them wholly determining the meaning. Other feminist linguists have analyzed texts in terms of the scripts and scenarios that seem to be governing the narrative events; for example, Crowther and Leith (1994) examined the way that in TV nature programs the use of stereotypical terms such as 'harem' to refer to animal groupings set up certain narrative pathways within the program, drawing on stereotypical assumptions about gender difference.

Thus, while feminist stylistics is still largely concerned with discriminatory practices within the process of production and reception of texts, it is much more subtle in its analysis and has recognized the need for more context-sensitive analyses that can draw on extratextual as well as textual features. Rather than simply analyzing pronouns or vocabulary choice, feminist stylistics analyzes the way that discourse-level phenomena such as reader positioning and point of view are constructed from linguistic features, and it is the complex interaction of these features that leads to particular interpretations of texts.

Stylistics: Corpus Approaches

M Wynne, Oxford Text Archive, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Stylistics, which may be defined as the study of the language of literature, makes use of various tools of linguistic analysis. Corpus linguistics is opening up new vistas for the study of language, and there are interesting similarities in the approaches of stylistics and corpus linguistics (*see* **Stylistics**). Stylistics is a field of empirical inquiry, in which the insights and techniques of linguistic theory are used to analyze literary texts. A typical way to do stylistics is to apply the systems of categorization and analysis of linguistic science to poems and prose, using theories relating to, for example, phonetics, syntax, and semantics. Theories and techniques of analysis from other areas of study, such as sociolinguistics, pragmatics, cognitive linguistics, and historical linguistics, are also brought to bear on texts. These approaches are typified by the work of Leech and Short (1981) and Short (1996).

The empirical approach of stylistics relies on the evidence of the language in a work of literature. Corpus linguistics, also an empirical approach to linguistic description, relies on the evidence of language usage as collected and analyzed in corpora (*see* **Corpora**). Burrows (2002) pointed out some underlying similarities of approach: "Traditional and computational forms of stylistics have more in common than is obvious at first sight. Both rely upon the close analysis of texts, and both benefit from opportunities for comparison." (The use of computers in the study of style is covered in other entries in the encyclopedia: *see* **Authorship Attribution: Statistical and Computational Methods**.) As linguists and stylisticians have become more aware of the possibilities offered by corpus resources and techniques, there have been increasing numbers of studies published that suggest that the coming together of these fields can be fruitful (e.g., Stubbs, 2005). It is therefore surprising that, apart from some important studies described here, there is little use of language corpora, or of the techniques of corpus linguistics, in the study of literary style. However, the use of corpora is becoming more widespread and more mainstream, as various barriers

Stylistics: Corpus Approaches

M Wynne, Oxford Text Archive, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Stylistics, which may be defined as the study of the language of literature, makes use of various tools of linguistic analysis. Corpus linguistics is opening up new vistas for the study of language, and there are interesting similarities in the approaches of stylistics and corpus linguistics (*see* **Stylistics**). Stylistics is a field of empirical inquiry, in which the insights and techniques of linguistic theory are used to analyze literary texts. A typical way to do stylistics is to apply the systems of categorization and analysis of linguistic science to poems and prose, using theories relating to, for example, phonetics, syntax, and semantics. Theories and techniques of analysis from other areas of study, such as sociolinguistics, pragmatics, cognitive linguistics, and historical linguistics, are also brought to bear on texts. These approaches are typified by the work of Leech and Short (1981) and Short (1996).

The empirical approach of stylistics relies on the evidence of the language in a work of literature. Corpus linguistics, also an empirical approach to linguistic description, relies on the evidence of language usage as collected and analyzed in corpora (*see* **Corpora**). Burrows (2002) pointed out some underlying similarities of approach: "Traditional and computational forms of stylistics have more in common than is obvious at first sight. Both rely upon the close analysis of texts, and both benefit from opportunities for comparison." (The use of computers in the study of style is covered in other entries in the encyclopedia: *see* **Authorship Attribution: Statistical and Computational Methods**.) As linguists and stylisticians have become more aware of the possibilities offered by corpus resources and techniques, there have been increasing numbers of studies published that suggest that the coming together of these fields can be fruitful (e.g., Stubbs, 2005). It is therefore surprising that, apart from some important studies described here, there is little use of language corpora, or of the techniques of corpus linguistics, in the study of literary style. However, the use of corpora is becoming more widespread and more mainstream, as various barriers

to the uptake of these approaches are overcome. Among the important areas of current activity, at least two different approaches (corpus annotation and norm analysis) can be discerned.

Corpus Annotation

Corpus annotation involves investigating a particular linguistic feature by taking (or making) a corpus – a sample or complete collection of the texts to be studied in electronic form – and conducting a thorough and exhaustive analysis of a particular feature as it occurs in this corpus. The results of the analysis are normally inserted into the electronic text as tags, or annotations. This activity of linguistic analysis and text annotation is similar to the procedures involved in word-class tagging, parsing, and other forms of linguistic annotation, which are widespread activities (*see* **Treebanks and Tagsets**). In this case, the interest is more specifically in the annotation of literary texts, or in the annotation of discursive and stylistic categories (see also Leech *et al.*, 1997). Indeed, these stylistic annotations may make use of and build on syntactic tagging already inserted in the corpus.

There are typically three outcomes of this process. First, the exhaustive analysis of a whole text or corpus is a more empirically sound procedure for discovering linguistic phenomena, compared to choosing examples; annotation of the electronic text forces the analyst to test and refine the system of categorization to account for all cases. Second, it is possible to extract statistics relating to frequency, distribution and co-occurrence of forms from the annotated text. Third, an annotated corpus is obtained, available for studies aiming to replicate or further develop the research, and usable for other areas of literary or linguistic research.

This approach of corpus analysis is exemplified by the work in the United Kingdom at Lancaster University, on the forms of speech, thought, and writing presentation in a corpus of texts. Leech and Short (1981) developed a system of classification for speech presentation in the novel (*see* **Speech and Thought: Representation of**). A project to test and refine this theory by attempting to apply it systematically to real data in a corpus was carried out over a number of years (Semino and Short, 2004) was carried out over a number of years. A corpus of modern British English narrative texts was constructed, representing fiction, news reports, and biographical writing. The corpus was then manually analyzed such that each occurrence of any type of reporting or presentation of a language event was categorized and annotated in the corpus. This enabled the analysts to test the adequacy of the theoretical model against real data. It forced them to account for all relevant phenomena found in the texts, not just the interesting examples that they had chosen to retrieve. It also made possible qualitative and quantitative comparisons between the different text types. Among the findings of the project were the discoveries that it is necessary to adapt the model so that there are different scales for the presentation of speech, thought, and writing, and that attempts to describe these phenomena together, as reported discourse presentation, risks missing the specificity of the presentation of the different modes. The distributions of the various forms were mapped across the text types, new categories were discovered, some categories were merged, and numerous correlations between rhetorical function and stylistic choices were noted (Semino and Short, 2004). It should be noted that this project contrasted literary and nonliterary narrative texts, and also contrasted 'highbrow' and 'lowbrow' texts within the genres. The assumptions underlying the category of 'literature' and its subtypes are by no means fixed or uncontroversial, and the techniques and practices outlined here were also applied to nonliterary texts and to texts whose 'literariness' is under investigation. Using corpora, Carter (2004) revealed linguistic creativity in everyday talk, and the work of the Lancaster stylisticians has continued with the analysis of spoken conversation (Semino and Short, 2004).

Norms, Deviations, and Collocations

A second approach, which makes use of a corpus for stylistic research, is to study literary effects in texts by using the evidence of language norms in a reference corpus. These effects can often be described as deviations from the norms of language use. The norms can be studied in a fairly straightforward way by looking in a large corpus. According to Stubbs (2005), "individual texts can be explained only against a background of what is normal and expected in general language use, and this is precisely the comparative information that quantitative corpus data can provide. An understanding of the background of the usual and everyday – what happens millions of times – is necessary in order to understand the unique." So, for example, if a particular word or phrase (or a particular type of usage or meaning of a word or phrase) is thought to be an exclusively literary form, then it can be searched for by automatic or semiautomatic procedures in a corpus of nonliterary texts in order to test this hypothesis.

A related area of increasing interest is the notion of 'semantic prosody.' Computational techniques can show patterns of co-occurrence of lexical items (collocations) and grammatical forms (colligations).

Several corpus linguists have used evidence of these patterns to study creativity in language, both in fiction and in everyday usage (Sinclair, 1987; Carter, 2004; Hoey, 2005; Stubbs, 2005), and the work of William Louw is of particular importance for stylistic studies.

Louw (1993), following on from the work of Firth and Sinclair, developed a new methodology for analyzing literary effects through the study of collocations. The method is based on the idea that certain words, phrases, and constructions become associated with certain types of meaning due to their regular co-occurrence with the words of a particular semantic category. To put it another way, the habitual collocates of a word give it a semantic coloring, which becomes part of the meaning of the word. For example, Sinclair (1987) discovered that the subjects of the phrasal verb 'set in' are almost always unpleasant things (e.g., *rigor mortis had set in*). This allows the possibility to evoke unpleasantness simply through employing the phrasal verb, without using other evaluative words or phrases. Louw (1993) described how the word 'utterly' is used in this way in the Larkin poem *First sight*, and developed a general theory of how the reader's feeling for semantic prosody can be exploited for ironic effect. Louw argued that an explanation or an analysis of the semantic prosodies associated with particular words is not generally accessible to our intuition. Such prosodies are essentially phenomena that can only be revealed computationally, and their extent and development can only be properly traced by computational methods.

Applications of the notions of collocation, colligation, and semantic prosody are also being developed in the current work of Michael Hoey, whose theory of lexical priming adds a cognitive dimension and can be used to account for creativity in language (Hoey, 2005). Speakers and hearers associate meanings with words not just because of their intrinsic meaning, but also because of the linguistic contexts in which they become habituated to speaking and hearing them. In this way words are primed for certain uses and meanings. For Hoey, creativity involves a selective overriding of the word's primings. The ways in which these primings are created by habitual usage can be found in corpora, and thus the source of the creativity can be studied in an empirical way. Interestingly, this work finds links not only between corpora and the study of style and creativity, but with cognitive aspects of language use as well (*see* **Stylistics, Cognitive**).

Resources, Tools, and Methods

If corpus linguistics and stylistics are so suited to each other in these ways, why is there not more work on the interface of these fields? Why do we still talk only about the potential for this area? There are several reasons why the potential for the use of corpora in stylistics has not been exploited to any large extent. For historical and institutional reasons, practitioners of stylistics, with training in more traditional methods of humanities research, may not be skilled or well equipped to use computers in their research. Furthermore, there is a lack of good quality, usable electronic texts and it is difficult to find and evaluate what is available. Though many texts can be found somewhere in electronic form, there is enormous variation in editorial principles, file formats, text-encoding practices, documentation, and quality control. This means that it is difficult to have confidence in the quality, consistency, and integrity of many electronic texts. Users often need a high level of familiarity with text encoding, tagging schemes, text processing, and text analysis software, along with an ability to deal with often complex generic computer hardware and software, in order to do the simplest things with texts on a computer. There is a lot of scope to develop textual resources and software to make research easier.

At a more philosophical level, there are trends of resistance to all of the more scientific, mathematical, and empirical studies of literature, and the use of computers may seem to epitomize the nonliterary and nonhumanist approach to literature. This view is dramatized in David Lodge's novel *Small world: an academic romance* (1985), when a researcher reveals to a novelist the results of a statistical analysis of his style, and as a result the novelist is unable to write creatively again. Though stylisticians are not generally antiscientific, there are some for whom computational procedures are a step too far. Although it can be argued that the use of computers for analyzing electronic versions of texts and for establishing evidence of linguistic norms in language use is merely a means of verifying and refining empirical statements and findings, some see the danger of research becoming preoccupied with computational procedures and with the encoding and annotation of electronic texts, leading to a regrettable lack of attention to textuality and the meaning.

Willie van Peer warned of the dangers of looking at language out of context:

> When stylistic features of a text have been transformed into numerical form, they acquire a status that actually prevents them from being perceived as language-for-communication as such. That is to say, in the very act of transforming textual qualities into counts, their essential process-like character is irretrievably lost. [. . .] Thus no level of (mathematical) sophistication is able to overcome the problem that the processes of meaning constitution have been eliminated before the analysis is undertaken. [Van Peer, 1989: 302]

Similar criticisms are voiced from within the field of corpus linguistics. Sinclair (2004), in particular, stressed the importance of not forgetting about the text and meaning.

Another important barrier to work with electronic texts is the fact that intellectual property rights, which aim to safeguard the rights of authors, present significant obstacles to academic research. In the real world (*pace* David Lodge) living writers are unlikely to be unexpectedly confronted with statistical analyses of their work, because making or copying an electronic version of their texts without permission is usually illegal.

Conclusion

As empirical work in linguistics increasingly makes use of language corpora, then stylistics and corpus linguistics are likely to continue to converge and overlap. Technical advances and improved resources are making the exploitation of electronic texts a more mainstream activity in stylistics. Large-scale projects to produce digital libraries of high-quality texts are underway, which should overcome many of the current difficulties in finding reliable texts on the web. The establishment of important international standards and guidelines for good practice in text encoding, such as Extensible Mark-up Language (XML) and the Text Encoding Initiative (TEI), should help improve the quality and reliability of literary texts and corpora in electronic form (*see* **Mark-up Languages: Text**). With standardization of formats and procedures, we can hope for powerful, flexible, and usable software tools for the analysis of literary texts and language corpora. Theoretical objections to the use of corpora in the study of the language of literature will doubtless remain, but it is to be expected that corpus linguistics will prove to be a useful addition to the stylistician's toolkit.

Stylistics: Pedagogical Applications

S Zyngier, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Definition

Pedagogical stylistics is stylistics applied to classroom contexts or any other context that involves the objective of promoting the learning of how language works. It deals with the practicalities of description, interpretation, and evaluation (Short, 1996) and abides by the distinction that has been made between 'stylistics applied' and 'applied stylistics.' Whereas the former involves works that develop theories of text processing, using real readers to test them, the latter identifies problems within a text and looks for a theory that best offers a solution (cf., Clark and Zyngier, 2003 for an overview). Pedagogical stylistics aims at promoting students' awareness of how language works formally and functionally so as to

enable them to perceive the subtleties of linguistic choices present in a text and the effects that these choices produce in readers. To this purpose, it uses tools derived from linguistics. The notion of text here may not be restricted to the written form. It can be extended to other cultural artifacts such as cinema and theatre. Equally, the notion of reader can be extended to viewers as well. Influenced by Critical Discourse Analysis and Language Awareness programs, more recent developments in pedagogical stylistics have been moving toward students' empowerment and emancipation in reading, responding, and writing. Based on Clark (1992: 118–119), by 'empowerment' pedagogical stylisticians mean "the process by which students become aware of what the conventions are, where they come from, what their likely effects are, and how they feel about them . . . [Emancipation is] using the power gained through awareness to act" in order to promote independent readers who are able to account for their interpretation from a linguistic perspective. Because it involves the five skills of language learning [reading, writing, speaking, listening, and thinking/processing (McRae, 2001)], pedagogical stylistics takes into account pragmatic, cognitive, and linguistic functions within social and cultural contexts.

Historical Background

Preservice programs for language teachers have had a long history and a longer bibliography for the many different approaches that have been developed since the advent of modern linguistics with Ferdinand de Saussure. The same does not apply to teachers of literature. Strangely enough, since the study of literary texts became a discipline in the 19th century, there has been a consensual agreement that the teaching of literary texts does not require training nor does analysis need explicit tools and strategies. According to Graff (1987: 1), "there were no 'academic literary studies' in America or anywhere else until the formation of language and literature departments in the last quarter of the nineteenth century," although "the use of literature as a vehicle of education goes back to ancient times." He adds: "But the idea that literature could or should be taught – rather than simply enjoyed or absorbed as part of the normal upbringing of gentlefolk – was a novel one and no precedents existed for organizing such an enterprise."

Since its institutionalization as a discipline to at least 30 years ago, the teaching of literature followed the long established model, which Freire (1970) called the 'banking education.' From this perspective, learners were seen as containers to be filled by teachers. The more the teachers filled the containers, the better educators they would be. The more passively the learners allowed themselves to receive information, the better the learners. In this context, learners were receivers and keepers of files. Training for the job was not considered relevant. In a typical literature class, the teacher pointed out **the** meaning of the text to a very silent audience of note takers. Research followed the Hermeneutic tradition, using theoretical developments in literary theory to produce new readings of texts. Empirical research was not contemplated.

When the literary text crossed the borders of the discipline to be used in EFL classrooms, the main objective was to enable learners to translate canonized texts in order to acquire a 'better' cultural model. Literary texts were then considered a kind of secular scripture. Merit – not the making – of the work was assumed. In this sense, Widdowson's (1975) *Stylistics and the teaching of literature* should be regarded as a landmark. It inaugurated a route linking the study of literature to the study of language through stylistics, creating a porosity, which allowed advances in one area to flow into the other. Since 1975, many works have contributed to change and have strengthened this link. A direct consequence has been the shift of focus from the work and the author to that of the language of literary texts. This change is indebted to the paradigmatic change introduced by the Russian Formalists in literary theory in the first quarter of the 20th century. If, on the one hand, this move concentrated on the materiality of language and inspired a series of textbooks on how to use literary texts in language classrooms, on the other hand, it has also favored the divide between what is called 'the study of literature' and 'the use of literature as a resource.' However, their most powerful contribution to pedagogical stylistics has been the notion of literariness. The interest now was not on **what** a text means but **how** it comes to mean.

Despite the move toward taking an interest in what makes verbal art, it was still believed that literary texts contained meanings that had to be extracted by the teacher and passed on to the student so as to make this student a 'morally better' person. As a consequence, the project of promoting independent critical readers constantly failed. These are questions that entail ideologically bound answers and involve educational, political, and economic decisions about the profession and the discipline.

Rosenblatt (1938) conveyed concern about the way teachers were being trained and literature was being taught, insisting on the need to elicit emotional responses from the students. Her work can be considered one of the first studies from a student-oriented perspective. But thus far it has not found its place in

a history of pedagogical stylistics. One of the problems of tracing this history arises from the fact that it is not too clear, having branched out in different centers at the same time. The three places where stylistics seems to have been taking shape in the late 1950s were the universities of Edinburgh (with McIntosh, Halliday and Firth), and of Hull (with Fowler), and the United States, as evidenced by the Indiana Conference organized by Sebeok in 1958, which resulted in Jakobson's 'political manifesto' for stylistics. But it was not until J. R. Firth's 1959 talk about style at the University of Edinburgh, followed by a British Council Conference, that the teaching of literature from a stylistics perspective really began to be systematized (Sinclair, 1966; Traugott and Pratt, 1980). By then, the use of literature as a resource for language learning had become a powerful method for EFL students. According to Carter and Walker (1989: 2), "non-native speaking students [of English] already possess in many cases an analytical knowledge of the target language and may therefore be more alert to the ways in which patterns of language are exploited in a literary text."

In Widdowson's seminal work, he pointed out that "the teaching of literature is concerned not with the transmission of facts and ready-made interpretations but with the development in the learners of interpretative procedures which can be applied to a range of language uses, both literary and nonliterary, which they encounter inside and outside the formal learning situation" (1975: 84) and provided practical exercises in literary understanding. This publication opened gateways to a large number of practical applications and checklists, which are used in many of today's classrooms.

Gradually, pedagogical stylistics became a language-based, student-centered, activity-minded, and process-oriented method of dealing with literary (and, in many cases, nonliterary) texts. Despite the strong British-oriented perspective of its beginnings, as evidenced in the choice of the title of Brumfit's collection (1983), by the end of the 20th century pedagogical stylistics expanded worldwide and is now being used in different countries and with different languages.

One of the central aspects of pedagogical stylistics is that it has always tended "to examine topics at the 'interface' of language studies and literary criticism ... [and in so doing, it] attempts to build bridges between these traditionally divided disciplines," as the blurb to Birch (1989: i) points out. Having once established this bridge, pedagogical stylistics sees how it can find a way into the classroom.

In short, pedagogical stylistics will always depend on the notion that style "crucially involves choice: it rests on the fundamental assumption that different choices will produce different styles and thereby different effects" (Verdonk, 2002: 6) in any kind of text. This perspective implies that pedagogical stylistics is concerned with all kinds of texts and that to become a critical reader the student will have to rely on formal features and functional significance (Wales, 2001).

Strands in Pedagogical Stylistics

Mainly interested in helping students develop a more systematic approach to texts, pedagogical stylistics has tended to use literature for the teaching of language rather than to capture the relationships between the social structure and the linguistic realizations of this social structure. Collie and Slater (1987: 10), for instance, stated that "the overall aim, then ... is to let the student derive the benefits of communicative and other activities for language improvement within the context of suitable works of literature." But there have also been more recent developments concerned with sensitizing students to the use of metalanguage in literature. In this respect, it draws on developments in Language Awareness and Critical Discourse Analysis to help students verbalize the ideological implications of linguistic choices. Empirical research in pedagogical stylistics has also been under way (cf., Clark and Zyngier, 2003 for an overview). Table 1 shows three different strands in which literary texts have been used in the classroom. These strands are not necessarily self-excluding, as much overlapping takes place.

Strand 1: The Content and Context of Literature

Most widely practiced by literature teachers with a hermeneutic tradition, Strand 1 is generally based on survey and historical inquiry. Among its main objectives we can list (some items on this list are from Durant and Fabb, 1990):

- to familiarize readers with acknowledged great works and writers;
- to study works of minority writers or other non-canonical production;
- to learn about the development of a national cultural tradition;
- to produce critical views on works seen as part of the history of literatures in English and/or of a literary tradition.

Besides anthologies, a representative textbook states that the objective here is to make students "actually read what are sometimes difficult texts, while at the same time giving them some help with literary history, biography, differences in genre, technical literary terminology and literary criticism" (Gower and Pearson, 1986: vi). Strand 1 in the

Table 1 Three strands of practice

	Strand 1: Content and Context	*Strand 2: Language through Literature*	*Strand 3: Literary Awareness and/or Intervention*
Objective	Learn about text, author, times, convention, history, etc.	Acquire knowledge of and about the language of literary texts (from language acquisition to understanding literary discourse)	Develop critical reading by manipulating texts
Methodology	Product-oriented; top-down	Product and process oriented; top-down/bottom-up, using linguistic theory to understand the workings and implications of language	Process-oriented; bottom-up
Bridges	Literary theory; cultural studies	Linguistics (descriptive and critical)	Linguistics (descriptive and critical); Cognitive Psychology
Materials	Anthologies; selected works, etc.	Textbooks with theoretical explanations; checklists; exercises	Textbooks with creative activities gradually leading into theory

teaching of literary texts, then, remains somewhat remote from the objectives of pedagogical stylistics.

Strand 2: Language through Literature

Teachers here aim at the study and acquisition of language through the medium of literature. That is, literature is seen as part of the language experience, which encompasses all levels: from phonology, grammar, and lexis to the investigation of the text as discourse and culture, or, to put it in other terms, from language acquisition to the understanding of the aesthetic and ideological implications of linguistic choices. This strand covers positions like that of Duff and Maley (1990: 3), whose aim is to "... explore further the use of literary texts as a language teaching resource rather than as an object of literary study as such," or the viewpoint that "the linguistic resourcefulness which typifies much literary discourse creates a valuable nexus for exploring forms, structures and concepts in English language" (Simpson, 1997: 2). But it can also be extended to positions like those of Carter and Long (1987: 1), who suggested that "the main purpose is to help students to use response to language as a basis for reading and appreciating authentic literary sources." The methods used are manifold and may include computational analyses. Tribble and Jones (1990: 72) showed how "the application of concordancing to the teaching of literature can be a fruitful area for classroom research and teaching/learning." On the other hand, it can also include nonliterary texts, such as advertisements. Another powerful resource has been checklists provided by textbooks, which connect lexical items to discourse frameworks in order to reveal ideological postures.

Strand 3: Literary Awareness and/or Intervention (Language Manipulation)

The main assumption here is that creative writing and metacognition are part of the literary experience. Strand 3 practices see sensitivity to the text as a process, which involves the reader as a constructor and experiencer. This is the fundamental principle that underlies the concept of Literary Awareness (Zyngier, 1994). This strand is based on the idea of intervention in tune with Pope (1995), who held that "The best way to understand how a text works is to change it: to play around with it, to intervene in it some way ..., and then to try to account for the exact effect of what you have done." This practice promotes writing and rewriting exercises to point out the creative role of the reader in the construction of any text. It tries to help learners consider what has not been done in order to highlight what has: a proposition that lies at the core of Hallidayan linguistics. It is believed that this method illuminates many issues such as textual appropriation, point of view, and ideology, enabling a more critical reading.

It must be pointed out that methodologies and approaches are affected by the contexts in which they are used. Although teachers and researchers today may have been sensitized to contextual influences, the tendency in pedagogical stylistics to focus on the microcosm of the classroom still prevails. Both language and literary awareness have contributed greatly to the sensitization of learners to linguistic phenomena and to the development of learners' metacognitive skills. Both attempt to empower learners. But empowerment requires more than the ability to think critically – it calls for critical action. Pedagogical stylistics cannot be restricted to a rationalization about methods and approaches.

The literature/language teacher must be aware of the social project in which and for which she or he is working. Teachers are part of the group Giroux (1992) called 'transformative intellectuals,' who promote an environment that enables the participants to reflect on their day-to-day life and the society to which they belong. In tune with Critical Discourse Stylistics, their methodologies should also aim at a textual reading, which discloses issues such as race, gender, class, rights, and institutions, how these relations and perspectives are expressed, and how they function in society (e.g., to persuade, dominate, express solidarity, warn). The challenge pedagogical stylistics must face is to provide a more culturally engaged and explicit perspective that may set the agenda for future research and practice. The main objective here is to move away from the fiction of a neutral and apolitical classroom and to concentrate on the context in which teaching takes place.

There are some basic questions about the educational system and the society that produces and reproduces social and cultural inequalities that affect and are affected by education that cannot be overlooked. Some of these questions are: How does one

- come to self-understanding?
- situate oneself in history?
- relate questions of knowledge to power?
- understand the limitations and constraints of institutions?

Thus far, very few scholars have been involved in the research of teaching literature and pedagogical stylistics. The field is vast and complex. Especially in a different cultural setting, as Kramsch (1993: 131) remarked, "Foreign language learners have to be exposed to different types of texts, from the most conventional to the most particular, but if they are eventually to find their own voice in the foreign language and culture, literary texts can offer them models of particularity and opportunity for the dialogic negotiation of meaning." Literature is the language of representation *par excellence* and, in line with critical linguistics, we can say that it is language used as social practice for social transformation. The study of literature as a critical experience stimulates a process of self-reflection and may lead the experiencer to perceive the ideologies and assumptions coded behind propositions. Pedagogical stylistics is an area of inquiry whose complexities are still to be probed.

Techniques

There are no formulas or clear-cut ways into a text. Because reading is involved, many of the techniques used for language teaching and developing reading skills are also used in a stylistics class. Different textbooks contribute with interesting and creative ways to help sensitize students to the nuances of a writer's use of language. Most of these activities are student-centered, aiming at students' awareness of how language is patterned, how it means and functions, and what effect it has on the reader. In general, the areas these techniques cover are as follows: word choice, syntax, cohesion, sound patterning, visual representation, semantics, dialect, register, genre, function, participants, processes, and circumstances (cf., Pope, 1995: 192–202) The techniques mostly used include cloze procedure (cf., van Peer, 1989: 282), rewriting from one discourse into another, gap-filling, creative writing, group quizzes, summarizing, turning one genre into another (e.g., prose into poetry and vice versa), reconstructing from fragments, scrambled words and sentences, ranking, predicting, role playing, writing projects, etc. It is not the type of technique or method that is used that matters. The challenge lies in testing their efficiency empirically.

New Directions

Out of the multiple possibilities of research areas and special interest for pedagogical stylistics, at least three can be pointed out at this stage:

1. Corpus analysis and new technologies, which show how the concern with significant patterns of language can be seen through computing and how these findings can help students support literary interpretations (Carter and Walker, 1989: 47–54). Computers are also being tested as a powerful tool for web-based pedagogical stylistics courses by researchers at the University of Lancaster (Short and Archer, 2003).
2. Empirical studies, which use the principles and methods of Empirical Science of Literature (cf., contributions to the Internationalen Gesellschaft für Empirische Literaturwissenschaft (IGEL) conferences, many of which have been published in journals such as *Poetics, Poetics Today*, and *The Empirical Study of the Arts*). Instead of subjective interpretations, studies in this area will borrow research instruments from psychology and the social sciences to gather data based on which readers' responses and interpretations can be understood and validated. More attention must be given to the way verbal art affects readers and how and why students are moved by texts. Studies on the role of affect in the processes of literary comprehension will necessarily contribute to the teaching of literature (Miall and Kuiken, 2002).

3. Cognitive stylistics and cognitive linguistics, a new and exciting field, which may illuminate how the student's mind works, how sense is made. According to Green (2000: 49), "analysis cannot be sufficient unless some form of 'mental representation' or 'mental space' is posited." Pedagogical stylistics may benefit from this area when investigating how students read, how they arrive at interpretations, how they process metaphors, and how their thinking is structured. This is especially relevant when comparing EFL/ESL students and readers of English as a first language in regard to metaphor processing and the understanding of irony. Are there universal mental structures or to what degree are they context dependent? Some applications of pedagogical stylistics, which stem from cognitive linguistics, have already found their way into the classroom (Stockwell, 2002).

These three areas show how pedagogical stylistics can be both challenging and inviting, remaining an integrated territory, where the student's affective, cognitive, cultural, social, linguistic, and historical dimensions are taken into account. Pedagogical stylistics remains true to its initial assumption: "to develop an awareness of significance beyond the immediate impression ... to give more precise focus to this awareness by drawing attention to textual features of the composition" (Widdowson, 2002: 162). What it has developed with the years is a concern of how texts function as social practice. In both situations, pedagogical stylistics offers students tools for substantiating their responses based on the way language works in context.

Stylistics: Pragmatic Approaches

B MacMahon, Sheffield Hallam University, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Pragmatics is typically defined in contrast with semantics. While both semantics and pragmatics are concerned with meaning, semantics deals with abstract and relatively stable meanings within the linguistic system, and pragmatics concerns itself with variable aspects of meaning which are derivable from utterances within contexts of use. As such, pragmatics can be, and often is interpreted, as covering a wide range of contextual factors, including, for some researchers, aspects of sociolinguistics, conversational turn-taking and narrative structure (see Traugott and Pratt, 1980), and cognitive poetics (see Radwańka-Williams and Hiraga, 1995).

Mainstream pragmatics; however, tends to focus on one or more of four models of language in use: Grice's cooperative principle and conversational maxims, Austin's speech act theory, Brown and Levinson's politeness principle, and Sperber and Wilson's relevance theory. These models are all originally developed with reference to nonliterary uses of language. In literary stylistics, pragmatic approaches fall broadly into two areas. First, there are those that take a general contextualized approach to understanding the reading of literary texts. These approaches overlap to some extent with reader response theories, and are outlined in the section on wider literary reading contexts below. Second, there are those that use the particular pragmatic models mentioned above and apply them to literary texts, sometimes innovating on the complexities of problem solving and developing the models themselves, in order to account for literary communicative processes. Within this second area, there is a further distinction to be made between work that applies the pragmatic models to examples of communicative interaction between fictional participants in literary texts, and work that addresses the nature of the interaction between writer and reader. Some work addresses both of these communicative situations, and indeed views the complexity of embedded interactions as characteristic of the literary text. Examples of the application of specific pragmatic models are outlined here in the sections on speech act theory, Grice's pragmatics, and politeness. The stylistic applications of relevance theory are discussed in a separate entry (*see* **Relevance Theory: Stylistic Applications**), and so are not considered here.

Speech Act Theory

In speech act theory, an utterance is defined as an illocutionary act with recognizable syntactic form. In addition, the utterance has a locutionary force relating to the intention of the speaker, and an effect on the hearer. Speech acts, according to the theory, fall into various categories such as representatives (i.e., stating what is believed to be a fact), verdictives (evaluating an event or situation), commissives (i.e., promising), declarations (bringing about a state of affairs, i.e., marrying). At different stages of its development, the theory has posited different sets of categories; and those given here are just a few examples. An important difference between types of speech acts is that some are truth conditional, and others simply have appropriateness conditions (also known as felicity conditions). Representatives are typically truth conditional in that the speaker is committing to the truth of his/her assertion, while declarations depend for their success on certain contextual factors; the declaration, 'I now pronounce you man and wife' is only valid if uttered in culturally appropriate circumstances by a person invested with the authority to marry.

In various pragmatic accounts of literature, a central concern is to define literature as what seems to be a rather a peculiar type of speech act; fiction appears to make assertions, but clearly without truth

Introduction

Pragmatics is typically defined in contrast with semantics. While both semantics and pragmatics are concerned with meaning, semantics deals with abstract and relatively stable meanings within the linguistic system, and pragmatics concerns itself with variable aspects of meaning which are derivable from utterances within contexts of use. As such, pragmatics can be, and often is interpreted, as covering a wide range of contextual factors, including, for some researchers, aspects of sociolinguistics, conversational turn-taking and narrative structure (see Traugott and Pratt, 1980), and cognitive poetics (see Radwańka-Williams and Hiraga, 1995).

Mainstream pragmatics; however, tends to focus on one or more of four models of language in use: Grice's cooperative principle and conversational maxims, Austin's speech act theory, Brown and Levinson's politeness principle, and Sperber and Wilson's relevance theory. These models are all originally developed with reference to nonliterary uses of language. In literary stylistics, pragmatic approaches fall broadly into two areas. First, there are those that take a general contextualized approach to understanding the reading of literary texts. These approaches overlap to some extent with reader response theories, and are outlined in the section on wider literary reading contexts below. Second, there are those that use the particular pragmatic models mentioned above and apply them to literary texts, sometimes innovating on the complexities of problem solving and developing the models themselves, in order to account for literary communicative processes. Within this second area, there is a further distinction to be made between work that applies the pragmatic models to examples of communicative interaction between fictional participants in literary texts, and work that addresses the nature of the interaction between writer and reader. Some work addresses both of these communicative situations, and indeed views the complexity of embedded interactions as characteristic of the literary text. Examples of the application of specific pragmatic models are outlined here in the sections on speech act theory, Grice's pragmatics, and politeness. The stylistic applications of relevance theory are discussed in a separate entry (*see* **Relevance Theory: Stylistic Applications**), and so are not considered here.

Speech Act Theory

In speech act theory, an utterance is defined as an illocutionary act with recognizable syntactic form. In addition, the utterance has a locutionary force relating to the intention of the speaker, and an effect on the hearer. Speech acts, according to the theory, fall into various categories such as representatives (i.e., stating what is believed to be a fact), verdictives (evaluating an event or situation), commissives (i.e., promising), declarations (bringing about a state of affairs, i.e., marrying). At different stages of its development, the theory has posited different sets of categories; and those given here are just a few examples. An important difference between types of speech acts is that some are truth conditional, and others simply have appropriateness conditions (also known as felicity conditions). Representatives are typically truth conditional in that the speaker is committing to the truth of his/her assertion, while declarations depend for their success on certain contextual factors; the declaration, 'I now pronounce you man and wife' is only valid if uttered in culturally appropriate circumstances by a person invested with the authority to marry.

In various pragmatic accounts of literature, a central concern is to define literature as what seems to be a rather a peculiar type of speech act; fiction appears to make assertions, but clearly without truth

conditions. Austin himself claimed that his theory did not apply to, "non-serious uses of language" such as poetry (see Levin, 1976). This view was elaborated by Searle (1979; see also Genette, 1990) and provoked a heated debate with deconstructionist critical theorists, who saw his characterization of literature as 'parasitic' upon the 'normal' use of language as a fundamental theoretical flaw (see Derrida, 1988; Rabinowitz, 1995). Others have taken a more constructive view, arguing that speech act theory can be developed in relation to literary communication.

Van Dijk (1976) does this by introducing the notion of speaker-hearer possible worlds, or S-worlds, which are relative, in terms of their truth conditions, to the individual speaker or hearer. The illocutionary force of the speaker is thus to change the S-world(s) of the hearer, but in literature there is a range of possible interpretations from which the hearer chooses the one that best matches his/her S-worlds. Literary speech acts, in van Dijk's view, do not function as acts whose intended outcomes are practical changes, but simply give access to the writer's S-worlds in the same way as saying how you feel or telling a joke might result in shared feelings and evaluations.

Levin (1976) discusses Ohmann's (1971, 1973) notion that literary utterances are mimetic of non-literary utterances, allowing the reader to construct a fictional situation that to some degree resembles his/her experience of reality. Levin, clearly influenced by generative grammar, goes further than Ohmann in proposing a higher-level implicit sentence in the deep structure of poems that announces its overarching illocutionary force of constructing a fictional world. The deep structure of the first line of Yeats's poem *Byzantium* is, for Levin, '[I imagine myself in and invite you to conceive a world in which I ask you] What shall I do with this absurdity?' with the words in parentheses omitted in the surface structure of the poem. Levin also suggests that literary features such as meter, rhyme, assonance, etc., in the poetic locutionary act signal the unusual nature of its illocutionary force.

Traugott and Pratt (1980) also take a speech act approach to the literary text, based in part on Pratt's earlier book (Pratt, 1977), giving an overview of work in this area, and like Levin and Ohmann, arguing that literary speech acts are mimetic of non-literary speech acts. They offer several possibilities for the illocutionary force of the literary speech act, such as the intention to give pleasure, to establish shared understanding and values, to teach, and conclude by suggesting that literature allows for many communicative functions. Further detail of the aspects of their approach based in Pratt's earlier work is given in the following section.

Grice's Pragmatics

The aspects of Grice's theory relevant to this discussion concern his model of conversational interaction as dependent upon a cooperative principle along with four conversational maxims. According to this model, speakers and hearers in successful conversational exchanges engage in cooperative behavior that is manifested by adhering to, and trusting that the other participant is adhering to the maxims of quality, quantity, relation, and manner. The maxim of quality requires that a speaker should assert only what she or he believes to be true. The maxim of quantity involves giving just the right amount of information for the purpose of the utterance, neither too much nor too little. The maxim of relation requires us to use appropriate utterances relevant to the preceding discourse, and the maxim of manner requires us to give separate pieces of information in a clear and helpful order. Of course, people do not always behave cooperatively in conversations, and according to Grice, the cooperative principle breaks down when participants fail to adhere to, or violate the maxims. Violating the maxim of quality, for example, results in lying. Even when the cooperative principle is upheld, the maxims can be flouted for particular effects. Metaphor and irony, for example, are said to flout the maxim of quality, giving rise to certain implicatures (implications discernibly intended by the speaker).

Pratt (1977), also summarized in Traugott and Pratt (1980), suggests that in the literary text, the cooperative principle is relaxed, and that this relaxation is enabled by the use of fictional characters and implied narrators (distinct from authors) as speakers. Referring to the third and fourth sentence of *Tristram Shandy*, Pratt reveals that Shandy's utterances violate all four of the maxims in numerous ways, implicating the author's intention to amuse the reader by enacting the ramblings of an uncooperative speaker. In another example, Pratt discusses Benjy, the retarded narrator of *The sound and the fury*, describing a game of golf in barely recognizable terms. Benjy's narrative fails to give enough information, and lacks indication of causal relationships between events. Pratt reads this as leading to an implicature on the part of Faulkner to the effect that Benjy's (or such people's) perspective is interesting because it is so different from our own.

Politeness

Brown and Levinson's (1987) model of politeness was developed to complement Grice's pragmatics, and to account for utterances which appear to violate the cooperative principle although participants still

appear to be engaged in cooperative behavior. Some violations of the maxim of quality, for example, involve lying to avoid being rude to a hearer, and indirect requests similarly seem to violate the maxim of manner in order to avoid causing offence with a more direct equivalent. In this model, Brown and Levinson invoke the notions of positive and negative face. In polite exchanges, participants attend to positive face needs by attempting to meet one another's desires, and attend to negative face needs by not impeding or imposing on these desires. Departures from the conventions of the politeness principle involve what are termed face-threatening acts. Just as adhering to the politeness principle might involve violating the cooperative principle, performing a face-threatening act might conform to the cooperative principle. The two principles might operate in tandem, but will often require different verbal behaviors.

Simpson (1989) makes use of the cooperative principle in an analysis of Ionesco's play *The lesson*. His argument is less to do with what Ionesco might be communicating through the use of stage characters than with the use of politeness strategies as indicators of character construction and development. He discusses the interaction between two characters, a professor and his pupil, who meet for the first time early in the play. Tracing their conversations through the acts, Simpson shows that the professor begins as a diffident character and gradually becomes dominant in the relationship, while the pupil, who makes a confident start, becomes passive. These changes are signaled primarily through their linguistic exchanges; the professor, for example, hedges and apologizes at the beginning of the relationship, but by the end is performing 'bald on record' face-threatening acts.

Leech (1992) takes a similar approach, using politeness theory in an analysis of Shaw's play, *You never can tell*, focusing in particular on the conflicting requirements of the cooperative and politeness principles, and examining the characters' attempts to resolve these conflicts in various ways, often to comic effect. Other uses of politeness theory in analyses of literary texts include works of Sell (1991b), Herman (1995), Kopytko (1995), and Lafuente Millán (2000).

Wider Literary Reading Contexts

Other pragmatic approaches address wider questions about the literary text and the literary reading process, making less use of the traditional pragmatic models, but still insisting on an attention to context and literary function as necessary to any explanation of literature. In several of these approaches explicit reference is made to literary pragmatics as a discipline that seeks to restore the significance of context in literary linguistics, and the consideration of works of literature as communicative acts, following the decontextualizing trends of New Criticism and the antiintentionalist ethos of late 20th-century critical theory, (see Sell, 1991a; Engler, 1991; McGann, 1991); Engler (1991), for example, rejects what he sees as one type of pragmatic approach to texts, which assumes determinate readings and commonality of readers' experiences, and privileges authorial intention, but he also rejects literary theoretical notions of interpretive communities (Fish, 1980) determining the direction of interpretation, arguing instead for a focus on the 'collaborative nature of textuality.' Lecercle (1999) sees the literary reading process as one that self-consciously raises questions about interpretation, arguing that reading itself *is* a kind of pragmatics.

How Literary Texts Work

Much of contemporary literary pragmatics is concerned to define literature as having a special functional and communicative status, yet at the same time operating on principles recognizably similar to those of nonliterary discourses. In this sense, a range of broadly pragmatic work approaches the literary text with the same questions as the speech act theorists of literature discussed earlier, but without recourse to the speech act model.

Van Peer (1991) introduces the notion of the homiletical texts and discourse, which occur outside of institutional situations. Literature, in van Peer's view, along with other texts and discourses, is homiletical, and is therefore functionally vague. Homiletical texts generally have one or two of three characteristics: they are reflective, socially cohesive, or entertaining. Literary texts can be defined as having all three of these characteristics, and this combination, along with its homiletical status is what makes literature unique.

Generic conventions are pragmaticized in Chapman and Routledge (1999) by using the idea that readers entertain a set of presuppositions in approaching different types of fiction; for example, detective fiction. Just as in other nonfictional types of discourse, presuppositions can fail. Presupposition failure in a conversation between friends might lead to communicative problems, and will probably violate truth conditions; 'My dog needs a walk,' existentially presupposes that I have a dog, and violates truth conditions if I do not. In literature, on the other hand, Chapman and Routledge argue there is 'greater pragmatic flexibility,' allowing for generic deviations from normative sets of presuppositions for communicative effect. Paul Auster's

postmodern novel *City of glass* is said to do this in various ways; for example, in manipulating narrative point of view, blurring the distinction between narrator and author and thus problematizing the notion of identity in a manner that would not be possible in nonliterary discourse.

What Literary Readers Do

The other side of the contextual question involves the role of the reader and the act of interpretation. Most work in this area challenges the notion that a text is simply a set of linguistic structures available to any reader able to decode them, and explores interpretive variability and the contextual factors influencing individual interpretations.

An example of this approach is Verdonk (1991), where the concern is with poetry as an act of communication that cannot only be determined by its form. The contexts relevant in a reading of a poem include, for Verdonk, the broad cultural environment of its reading, and the reader's knowledge of literary conventions and literary form. Formal features of literary language such as parallelism and deviation are said here to trigger pragmatic processing, but the direction of this processing will be determined by its context. For a more specific and localized account of the relationship between linguistic form and interpretation, see Alonso's (1995) analysis of responses to a short story by Katherine Mansfield.

The reader's cultural environment is a significant contextual factor in the interpretation of literary texts. A detailed account of culturally influenced reading is given in Ben-Porat (1991), with reference to Israeli readers' interpretations of a 12th-century poem that describes a city of beauty and grandeur, without naming the city as Jerusalem. Ben-Porat shows how Israeli students given an unseen exercise on the poem easily interpret the reference to Jerusalem, in spite of a rather different experience of the contemporary city. Their readings are attributable to a culturally constructed concept of the city, shaped, in part, by descriptions in other works of literature.

Avant-garde, modernist, and postmodern texts, in which forms and conventions, including linguistic forms, are manipulated to an extent not usually encountered in nonliterary contexts, pose a challenge to the reader of literature. The interpretation of these texts also holds particular interest for the literary pragmaticist. Enkvist (1991); for example, considers more experimental literary texts, such as Dadaist poems, which defy interpretation in the deviation from recognizable linguistic form. He suggests that these genres are simply the endpoint of a literary function which aims to maximize the work entailed in the reading process. For Enkvist, most utterances involve intelligibility (linguistic well-formedness), comprehensibility, and interpretability, but literature, to varying degrees, prioritizes interpretability, sometimes at the expense of the other two factors. The successful reader of literature is able to construct a text world that makes some sense in spite of this difficulty, and the literary text thus gives rise to aesthetic tension.

Conclusion

The examples of pragmatic approaches to literature given here show that the range and purpose of literary pragmatics is wide. Some approaches take the technical apparatus of nonliterary pragmatics as a starting point, arguing that, with some adjustments, a case can be made for considering literary texts in terms of speech act theory, the cooperative principle and the politeness principle. Others abandon the pragmatic models altogether, but still aim to characterize literary effects with reference to literary function and the literary reading process. A central feature in all of the work is its attempt to establish literary works as acts of communication that relate, sometimes obliquely, to acts of communication in nonliterary discourses.

Subcultures: Background

One of the assumptions implicit in the term 'subculture' is the lower, subordinate, or deviant status of social groups that receive this label. Many groups labeled as subcultures have lower social status due to class, ethnicity, linguistic background, or other social factors (e.g., poor and working class people, ethnic minorities). In other cases groups considered subcultures see themselves or are seen by others as deviant (e.g., gays and lesbians, drug users). Unlike communities, subcultures are characterized by their transience, their informality, and the absence of the sort of kinship ties that typify communities. They are commonly perceived to embody an oppositional stance to the normative ideals of mainstream adult society (Thornton, 1997). In an attempt to refine the term subculture, Gordon (1947) lists speech patterns, particularly pronunciation and inflection, and clothing as the two most readily identifiable indices of subcultures.

The study of subcultures has its origins in the Chicago School during the 1940s and 1950s and reflected a sociological interest in human behavior in an urban environment, especially as this manifested itself in deviant and delinquent behavior (Cohen, 1955). Subcultures were seen as the key to explaining and understanding deviance as normal behavior. As a result, quite of bit of the research focused on urban male youth gangs and jazz musicians (Becker, 1963).

Subcultures and Countercultures

Subcultures: Background

One of the assumptions implicit in the term 'subculture' is the lower, subordinate, or deviant status of social groups that receive this label. Many groups labeled as subcultures have lower social status due to class, ethnicity, linguistic background, or other social factors (e.g., poor and working class people, ethnic minorities). In other cases groups considered subcultures see themselves or are seen by others as deviant (e.g., gays and lesbians, drug users). Unlike communities, subcultures are characterized by their transience, their informality, and the absence of the sort of kinship ties that typify communities. They are commonly perceived to embody an oppositional stance to the normative ideals of mainstream adult society (Thornton, 1997). In an attempt to refine the term subculture, Gordon (1947) lists speech patterns, particularly pronunciation and inflection, and clothing as the two most readily identifiable indices of subcultures.

The study of subcultures has its origins in the Chicago School during the 1940s and 1950s and reflected a sociological interest in human behavior in an urban environment, especially as this manifested itself in deviant and delinquent behavior (Cohen, 1955). Subcultures were seen as the key to explaining and understanding deviance as normal behavior. As a result, quite of bit of the research focused on urban male youth gangs and jazz musicians (Becker, 1963).

In the 1970s and 1980s, there was shift toward structural explanations for the emergence of subcultures. The Birmingham Centre for Contemporary Cultural Studies (CCCS) moved away from the study of youth gangs to focus primarily on style-based working-class youth cultures such as punks, skinheads, Teddy boys, mods, and rockers (Gelder and Thornton, 1997). The work of Hall and Jefferson (1976), Hebdige (1979), Clarke (1976) and others interpreted the emergence of youth subcultures as a response to the breakup of traditional working-class communities and their relocation to modern housing estates during the 1950s (Cohen, 1972). Criticism of the CCCS focused in part on the lack of concern with the involvement of girls and women in subcultures (McRobbie, 1980). McRobbie (1984, 1994) went on to describe how girls and young women have long used style as a form of resistance to mainstream sexual norms and notions of femininity.

In the 1990s and 2000s, the term subculture came to be used in a much wider sense to describe any group of people who orient to norms of behavior, values, beliefs, consumption patterns, and lifestyle choices that differ to varying degrees from those of the dominant, mainstream culture. It could describe loose groupings of people with shifting boundaries who share little more than similar lifestyles or consumption patterns (e.g., metrosexuals, Nascar dads). It can also include groups of people who share sexual practices (e.g., LGBT, or lesbian, gay, bisexual, and transgendered people), or spiritual beliefs (e.g., Neo-pagans, Wiccans).

The increasingly broad scope of what counts as a subculture has led some researchers to question its utility and to call for a reconceptualization or replacement of the term (Muggleton and Weinzierl, 2004). The breakdown of identities rooted in class, ethnicity, gender, and locality has led to the emergence of more fleeting, temporal 'tribal' identities (cf. Maffesoli, 1996). Bennett (1999) argues that contemporary style-based youth cultures lack the forms of organization, cohesiveness, and stability of subcultures and should more accurately be called 'neo-tribes.'

Setting aside theoretical debates about the continued efficacy of the term, we can identify several general categories of people who are labeled with it: those who are oriented to a set of shared ethnic practices (e.g., Italian Americans), those who are oriented to a set of beliefs or values rooted in religious beliefs (e.g., Janists, Sunni Muslims), those whose members share a number of regional cultural practices (e.g., Bavarians in Germany), and those who are defined largely in terms of fashion, music, and lifestyle consumption patterns (e.g., Goths, video gamers, ravers, straight edge).

Lifestyle-based subcultures (especially those centered around music and clothing) are probably the most widely recognized type in postmodern industrialized societies, although they lack the cohesion and stability of traditional subcultures. Young people who orient towards a hip-hop lifestyle (characterized by consumption of rap music and a baggy dress style) may also participate in wider club culture and enjoy techno music. The choices available to consumers allow them to experiment with different identities and to select lifestyles that are not indicative of a specific class background (e.g., the New Age Travellers discussed in Hetherington, 1998). Bennett (1999) says that this signals a new sort of subcultural tradition in which there is less of a fit between visual style and musical taste.

When subcultures become recognized and identified by media elites, marketing, and/or academics, they are assigned a name that may eventually enter popular discourse (e.g., Modern Primitives). In some cases this naming accompanies a moral panic or burst of sensationalist articles and discussions in the popular media surrounding a particular subculture (e.g., British soccer hooligans, Goth culture in the wake of American high-school shootings; see Cohen, 1987). Often times the names given to subcultures have historical origins. The term 'hooligan,' now used to describe rowdy bands of soccer fans, originated in 19th century Britain (Pearson, 1983). Lanham (2002) recycled the term 'hipster' from the 1950s Beat Generation to describe groups of politically liberal, fashion conscious, middle-class American college graduates who began gentrifying undesirable urban neighborhoods in the 1990s. He also attributed to them an entire slang, including terms like 'deck' (cool) and 'fin' (not cool) whose currency among hipsters is questionable.

Subcultures are increasingly translocal, that is, not limited to a specific country or region. The Internet and the globalization of media and mass consumerism allow subcultural trends to spread rapidly from one country to another. Hip-hop culture, a style- and music-based youth subculture that emerged in New York City in the 1970s, has spawned local rap artists and rap scenes all over the United States, Asia, and Europe (Boucher, 1998; Cornyetz, 1994; Cutler, 2002). The Internet also allows for the creation of virtual subcultures made up of individuals who never meet face-to-face (Bassett, 1995), such as the large, on-line subcultures of people devoted to developing the languages of the novelist J. R. R. Tolkein (Qenya, Elvish and others) or languages from the Star Trek television series, such as Vulcan.

In the postmodern age, subcultures are increasingly lifestyle oriented. People rely on lifestyle magazines

(e.g., *Outdoor Magazine, O, Car and Driver*) and the products these magazines promote in order to express their subcultural affiliations. Wheaton and Beal (2003), for example, point to the role that windsurfing and skateboarding magazines play in providing and circulating cultural knowledge and displaying subcultural capital.

The Language of Subcultures

Subcultures (and countercultures) often have distinctive language patterns. The way people talk expresses an affiliation with a certain group and set of social practices, and a simultaneous rejection of others. Speech markers (speech features that carry social significance, cf. Labov, 1972) are one of the ways that members of a subculture can signal their affiliation with the group. Speech markers may include an argot or a set of words and expressions unique to the group. Surfers have special terms like 'dropping in' to describe the act of stealing someone else's wave. Heroin addicts refer their drugs as 'shit' or 'junk' (Polsky, 1967). In other cases, the language marking a subculture may also include phonological, morphosyntactic, prosodic, and paralinguistic patterns. Aside from a whole set of hip-hop terms, some hip-hoppers use grammatical forms that originate in African–American English, such as the zero copula (e.g., You___ the man). Immigrant subcultures have speech patterns that reflect their native language heritage as well as different patterns of social interaction. Labov (1972) describes how the *r*-less pronunciation of 'car' and 'cart' in New York City is indicative of lower-class speech.

In some cases the speech markers groups use to distinguish themselves are remarkably subtle. Eckert (1989) focuses on two groups of oppositionally defined students in a Midwestern American high school: 'jocks,' who orient to middle-class values and the corporate culture of the school, and 'burnouts,' who identify with working-class culture and the community outside the school. She found that a young person's affiliation with each of these categories was positively correlated with vowel patterning. Jocks and burnouts express their respective stance towards school culture in their use of the vowel (uh) as in 'butter': Jocks tend to use the standard central variant [ʌ] whereas burnouts are more likely to use the back rounded variants [ɔ] or [ʊ].

In other cases, linguistic features may occasionally index particular stances like toughness or intellectual superiority. Bucholtz (2001) describes the linguistic practices of science fiction/fantasy fans, young people who consume a range of science fiction comic books, novels, films, and television shows, and participate in fantasy role-playing games. Linguistically, members of science fiction/fantasy subcultures mark themselves by way of 'superstandard' English that indexes intelligence, humor, and nonconformity as well as opposition to dominant colloquial styles.

Countercultures

Countercultures are often described as radical groups of people who reject established social values and practices and who embrace a mode of life opposed to the mainstream. Countercultures emerge in the wake of dramatic economic and social developments. They are reactions to social dislocation and alienation from society. Countercultures share many similarities with subcultures, but rather than modifying dominant values and norms, they seek to reconstruct an alternative social order that rejects or subverts those values and norms. Some historical examples include the Bohemians (19th century European artists, writers, and disenchanted people of all sorts who wished to live a nontraditional lifestyle), or the Beatniks (a group of young artists and writers in New York City who espoused nonconformity and existentialism during the 1950s). Currently the term has its strongest historical associations with those who advocated a communal or nomadic lifestyle, renounced corporate nationalism and the Vietnam War during the 1960s and 1970s, and embraced aspects of Eastern religions such as Buddhism and Hinduism (i.e., the hippies). The late 1960s also spawned a number of radical political movements committed to the eradication of institutionalized racism and government oppression in the United States (the Black Panthers, the Weathermen, and the Symbionese Liberation Army). The punks in Britain and the United States during the 1970s and 1980s could be classified as a counterculture, although this term is not usually applied to them. Many punks rejected consumerism, espoused anarchy, and lived illegally in squats or abandoned buildings.

There have been few examples of movements that could be classified as countercultures in the 1990s and 2000s. One is the anticorporate globalization movement that organizes protests (e.g. Seattle, 1999; Genoa, 2001) against transnational corporations and trade liberalization institutions such as the World Trade Organization, the World Bank, the International Monetary Fund, and the G8. By some estimates well over one million people attended anticorporate globalization protests between the 1999 protest in Seattle and the Genoa action in 2001, excluding the millions participating in the anti-IMF general strike in Argentina in May of 2000 (George *et al.,* 2001). But as is characteristic of postmodern subcultures, these

groups are very fluid, difficult to define, and lacking in an identifiable organizational structure.

Countercultural markers such as tattoos, body piercing, drug use, and unconventional clothing have become so much a part of mainstream, commodified youth culture that they have lost much of their subversive value. The increasingly sophisticated marketing industry is ever more quick to identify, label, and package nonconformist lifestyle trends, quickly rendering them part of the mainstream. One way that a counterculture can express its disaffection with mainstream norms is through the adoption of an antilanguage involving the conscious distortion of conventional language via metathesis (altering the order of sounds or syllables), mixing, borrowing, or by changing the meaning of words. Some examples include 'verlan,' a youth language in France involving the reversal of syllables, and the language of urban youngsters ('wahuni') in Dar Es Salaam consisting of arcane instances of linguistic mixing, borrowing, and relexification in Swahili, English, and other languages (Blommaert, 2003).

Conclusion

As Muggleton and Weinzierl (2004) argue, 'subculture' continues to be a convenient way to describe more unconventional aspects of youth culture, but it does little to help us comprehend the diverse range of youth groups in today's so-called postmodern world. Scholarly work on subcultures must take into account calls to reformulate and replace outdated notions of subcultures so that they are more applicable to the experiences of youth in the 21st century.

Subgrouping Methodology

C Reiss, Concordia University, Montreal, Canada

© 2006 Elsevier Ltd. All rights reserved.

Given a group of related languages (in this discussion, the term 'language' is used in the somewhat inexplicit sense familiar from historical linguistics, and not in the sense of a mental grammar, as in the generative tradition), that is, languages whose surface forms can be derived by regular sound correspondences from a reconstructed ancestor protolanguage, the task of subgrouping is to determine which of the languages share portions of their history to the exclusion of other members of the group. For a group of languages A, B, C for which we can reconstruct Proto-ABC, the claim that A and B form a subgroup means that there is an intermediate protolanguage Proto-AB between the attested languages and Proto-ABC, and that in the period from Proto-ABC to Proto-AB, there was no distinction in what would ultimately become these two languages – they were the same language.

In principle, it is simple to determine whether the AB versus C subgrouping is valid. If there are any innovations shared by AB in their history from Proto-ABC to the attested languages, and there are none shared by either A or B with C, then A and B form a subgroup to the exclusion of C. Only shared innovations, and not shared retentions from the protolanguage, are relevant to determining subgrouping, since shared retentions in no way reflect a common period of development to the exclusion of other languages. In other words, assuming an AB subgroup, it may be the case that A and C share features retained from Proto-ABC due to the fact that B has undergone innovations subsequent to the split of A and B.

It follows from the irrelevance of shared retentions to the subgrouping problem that the **number** of traits shared by two languages can have no bearing on subgrouping argumentation. It may be the case that A and C look very similar, in terms of their phoneme inventory, for example, whereas B has a very different inventory, with little in common with either A or C. However, if the commonalities of A and C reflect retentions from Proto-ABC, and the traits of B reflect innovations since the A-B split, then the high number of traits shared by A and C has no bearing on subgrouping.

While the logic of this methodology is straightforward, its application in practice can be quite difficult. Determination of shared innovations proves to be difficult since the most common types of language change, by definition, happen over and over again. So, it is possible that A and C both show, say, assibilation of *t to [t^s] before [i], but that this reflects parallel but independent events after the split of AB versus C.

The ordering of changes can sometimes be used to exclude the possibility that a change in two attested languages reflects a shared innovation. If it can be shown, for example, that the assibilation in B must have followed another innovation that belongs strictly to B, and not to A, then we can conclude that the assibilation in the two languages reflects two independent changes.

Even this method is subject to complications, however, since a change may result in a productive phonological process. Suppose that A and B do in fact inherit a shared assibilation change. Now suppose that the change produces a synchronic phonological rule /t/ > [t^s]/___i. If, in a subsequent change, B simplifies consonant clusters, so that *tri ends up as *ti, then the latter form undergos assibilation to [t^si]. The cognate word in A, which does not have the cluster simplification, will be [tri]. The form in B shows assibilation that crucially depends on a simplification subsequent to the split of A and B, but the rule of assibilation is a common inheritance.

Another difficulty that arises when a shared innovation is obscured by further developments in one of the languages can be illustrated as follows. Suppose that word-final *n reconstructed for Proto-ABC is lost in both A and B, but not in C. This looks like a shared innovation, but suppose that B also has lost Proto-ABC *m, which is retained in A. Now we have to decide if, in the history of B, there was a single change involving the loss of both final nasals, and thus independent of the change in the history of A, or whether A and B share the loss of final *n in their history, with the subsequent loss of *m in B being a later change. This latter hypothesis clearly complicates the historical phonology of B, but may nonetheless be correct. Again, we can try to find ordering arguments to show that, in B, the two nasals were lost at different times, but such arguments may not be forthcoming.

Subjective and Objective Measures of Variation

N Niedzielski, Rice University, Houston, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

Within the field of sociolinguistics, the study of language variation has relied predominantly on *objective* measures of variation. That is, researchers examine the forms that tokens (or *variants*) of a variable take, the percentage of occurrence of each variant (in terms of both language-internal and language-external factors), the constraints on that occurrence, and the distribution of a given variable across social groups. A complementary approach to examining variation involves *subjective* measures. Such examination requires the measurement of subjects' impressions of and attitudes toward language variation, often in conjunction with objective measures in either the subjects' varieties or the varieties of the speakers used as stimuli.

There have been several different methods of examination of subjective variation, encompassed by a large volume of research on language attitudes. One of the earliest methods was the matched guise technique (Lambert, 1966). This method involves the use of a single speaker in two (or more) 'guises,' with the presumption that if different reactions are accorded to different guises, then subjects are reacting solely to language varieties, rather than to idiosyncratic qualities in speakers' voices. Since this work, many such studies have been undertaken (see Giles and Coupland, 1991), and a great deal of work in the social psychology of language continues to measure subjective variation. For instance, work using Giles' Communicative Accommodation Theory framework (Giles, 1973) has demonstrated that speakers often accommodate their speech toward *perceived* (or subjective) features, rather than actual, objective features in interlocutors' varieties (Beebe, 1981).

Within the field of sociolinguistics, researchers looked at subjective variation using a number of methods. Perceptual dialectology examines subjects' subjective placements of dialect boundaries. Among the many language attitudes studies discussed in Lippi-Green (1997) is Rubin (1992), in which subjects perceived nonnative features in the speech of a speaker and performed worse on comprehension tests if they thought they were listening to a foreigner, compared to those who thought the speaker was American.

Similar to Rubin (1992), Williams *et al.* (1972) revealed that teachers perceived nonstandard features in the speech of children if they were led to believe that the child was African-American, but not if they were (correctly) told that the child was White. Niedzielski (1999) showed that subjects perceive nonstandard features in speakers' speech if they believe that the speaker belongs to a group for which that feature is a stereotype. Furthermore, this study revealed that subjects' self-stereotypes lead to misperceptions of features in their own variety.

Social factors have been taken into account in work on speech perception in phonetics. For instance, Janson (1986) shows that categorical perception is affected by language change, such that younger speakers undergoing the change perceive phonemic category boundaries differently from older speakers.

These studies indicate that there is not a strict correlation between actual variation in a speech community and the variation that is perceived by its speakers (and others). The measurement of subjective variation is important not only for linguists examining areas such as speech perception and language change, but also for researchers in areas such as education, speech therapy, and language policy.

Subjects and the Extended Projection Principle

J van Kampen, Utrecht Institute of Linguistics, Utrecht, The Netherlands

The Subject

The Intuitive Notion

Aristotle (350 B.C.) defines subject and predicate as the counterparts that form a simple sentence. There is in a simple sentence a binary split between a referential naming part, the subject, and a characterizing part, the predicate.

The binary split is grammatically marked in various language-specific ways. Take (1) as an example.

(1) $[[\text{Mona Lisa}]_{\textbf{subject}}\ [\text{is smiling away}]_{\textbf{predicate}}\ ]_{\textbf{proposition}}$

The left-hand part is the subject. It is a reference carrier and represented by a name, a pronoun, or a nominal phrase. As reference carriers, all subjects get the same label (DP in generative grammars). The right-hand part is the predicate. It may be represented by a variety of categories. Its function is not referential but characterizing.

The more recent perspective on the subject–predicate construction is attributed to Frege (1879) and it develops in the following way. The predicate can be considered as a function that accepts the referential subject as its argument. The application of the predicate function to the subject argument equals the statement or proposition. This entity (proposition) has a new and distinctive characteristic. It has a truth value. It is true or false. From this point of view, the predicate function projects subject arguments on truth-valued statements. As a function, the predicate may be said to represent a property. The predicate property corresponds with an indefinitely extended class of imaginable possible events or state of affairs. All members of the set share the same characterizing property, which is given with the predicate.

The predicate assigns a property to the subject. However, the subject–predicate construction is more than property assignment only. Property assignment to the subject has an additional specific function. It instantiates the predicate in a single case such that the new construction must be true or false. This is crucial. The relation in a subject–predicate construction creates a new syntactic entity and that entity is distinguished by its truth-value property. As Aristotle (350 B.C.: Book I) pointed out, this truth-value property is the new and decisive characteristic of the subject–predicate construction.

Property Assignment

Property assignment as such needs not have the truth-value effect. There may be other reference-carrying parts within the proposition. They attract a property assignment as well, but they are not subjects. For example, the property assignment to 'any visitor' in (2) limits the predicate set, but is not offered as a point of instantiation.

(2) [Mona Lisa]-DP is smiling away at any visitor

The example in (2) can be rephrased as in (3).

(3) [Any visitor]-DP is being smiled away at by Mona Lisa

The predicates in (2) and (3) are somewhat differently qualified (active versus passive), but the two persons referred to, 'Mona Lisa' and 'any visitor', get assigned the same properties, say the charming one and the charmed one. These properties that a predicate head assigns to its arguments are commonly called theta roles. Each one of the theta roles is fit to function as a point of instantiation and a point to check for a true/false value, but if and only if it is assigned in the subject construction. This much may suffice to highlight the difference between implied property assignment to the nonsubject arguments and the explicit property assignment to the subject argument.

The subjects in (2) and (3) have a different property assigned to them by the predicate. The subject 'Mona Lisa' in (2) gets the property agentive argument. The subject 'any visitor' in (3) gets the property receiving, beneficient argument. Yet, although different, the subjects have their grammatical function in common. Each one brings its property (implied by the predicate) to the fore as the decisive moment for the truth value of the subject–predicate construction.

The Extended Projection Principle

So far, age-old plausibility considerations have been used to argue that a true/false value constitutes the defining requirement for a proposition. The logical truth-value requirement reappears as a grammatical well-formedness condition. The predicates in grammar require a local element that indicates and licenses their predicate status. At the same time, the predicate licenser involves the grammatical requirement that a subject should be present. If the DP subjects in (1)–(3) were left out, the remaining predicates would of course no longer function as parts of a proposition. At the same time, the predicative remnants are, without

any logical reflection, no longer interpretable as acceptable clauses either. That well-formedness failure can be described in mere grammatical terms. One must say that the 'smiling' predicates in (1)–(3) contain a local licenser, the auxiliary/copula 'is'. Let the category of the auxiliary/copula be labeled as a head I^o (Inflection). I^o projects into a phrase IP and it selects in (1)–(3) the predicate as its complement. At the same time, the auxiliary/copula element requires a specifier DP phrase on the left. See the phrasal diagram in (4). The IP phrase requires a specifier DP. Consequently, the grammatical well-formedness conditions of the IP relate predicate and subject, as respectively the complement and the specifier of I^o.

(4)

The definition of subject and predicate as specifier and complement of an I^o projection is known as the Extended Projection Principle, often abbreviated as EPP (Chomsky, 1981: 40f; Rothstein, 1983; Chomsky, 1986: 166). One could consider the I^o projection as the canonical form for the subject–predicate construction. The propositions of logical form correspond with the I^o projection in grammatical form. In general, a head X^o with lexical content will license its arguments as complements within its XP phrase. This is the Projection Principle and it serves to guarantee a semantically coherent interpretation of XP phrases. In addition, the predicate XP phrase will have a licenser I^o that announces a special or privileged argument position outside of the lexical predicate phrase in (4). In a sense, the licenser I^o extends the XP domain of argument licensing with Spec.I.

Configurational Prominence of the Subject Argument

A Uniform Configurational Prominence (EPP)

The Extended Projection Principle implies that all points where a speaker commits himself to an explicit truth value must be of the same IP type and form. Grammar would not admit to degrees of subjecthood or to degrees of explicit predicate instantiation. All cases of the subject–predicate relation are to be treated as configurations of an extended projection IP. If it were possible to define the subject in a uniform configurational way over all constructions and all languages, the propositional logic of natural language would be straightforward. Moreover, and grammatically more interestingly, if subjecthood were definable by a uniform configurational prominence throughout, secondary subject properties could be made to follow from that same configurational prominence.

Such secondary subject properties are, for example, the subject's antecedency in anaphoric phi-relations {verbal agreement, reflexivity, control} in (5) and the wider scope of quantifiers in (6).

(5) She convinces **herself** **to** visit the Louvre

(6) each woman considered some pictures
(for every woman, there are at least some pictures that she considered)

The phi-feature antecedency and the wider quantifier scope follow if the subject c-commands the other arguments. The subject strictly c-commands the predicate if it is within the first phrasal configuration above the predicate (Reinhart, 1976; see also Chomsky, 1986: 164f). It may now follow from configurational prominence that any subject is the possible antecedent for further arguments in the predicate, whereas the reverse cannot hold. The sentence in (7a) cannot be acceptably rephrased as the one in (7b).

(7a) Mona Lisa liked herself
(7b) *she, herself, liked Mona Lisa

A quantifier on the subject may easily lead to a distributive reading for some argument, whereas the reverse does not hold. The sentence in (8a) will as such never be intended to mean that one should think of one and the same set of pictures as in (8b) (see Reinhart, 1983: 193).

(8a) each woman considered some pictures
(8b) *there were some pictures considered by each woman

In principle, grammatical properties of the subject should be derived from its configurational prominence. A further discussion of the EPP from various points of view is given in Svenonius (2002).

Secondary Predicates

The uniform configurational view on subject prominence (EPP) postulates a simple relation between grammatical form and the propositional status of a clause. The question is whether the EPP can be maintained. Here is the problem. Each natural language contains a score of various subject–predicate relations and the I^o projection for the EPP is hardly ever present in an obvious way. Moreover, English is comparatively

rigid on phrasal configurations, but other languages are less so and some seem to have hardly any phrasal configuration at all. For this problem and a defense of a configurational approach, see Baker (2001). Does then at least English have a phrasal configuration sufficiently tight to allow a uniform definition of the subject–predicate relation? It may be, but only by an extensive appeal to the theory of grammar. The originally intuitive notion of subjecthood is traded in for the EPP, and the presence and absence of an EPP configuration can only be considered within a whole theory of configurational syntax. Consider the bracketed parts in (9) and (10). They do suggest a predicate that is related to a subject, whereas an IP split as in (4) seems to be lacking most of the time.

(9a) finite verb subject
she [– smiles away]
(9b) infinitival raised subject-to-subject
she seems [– to smile at me]
(9c) infinitival raised subject-to-object
I believe her [– to smile away]
(9d) infinitival accusative subject
I saw her [– smile at me]
(9e) infinitival subject in *for/to* complement
I long for her [–to smile to me again]
(9f) subjects in *for/with* absolutives
with her [–smiling] my day was made
(9g) small clause resultative subject
that smile made her [– my heroine]
(9h) small clause subject with '*as* predicate'
I consider her [– as a flirt]
(10a) infinitival controlled subject
she intends [– to flirt]
(10b) predicate adjunct
Mona Lisa did not consume the carrots [– unwashed]

The bracketed predicates marked by a finite head (9a) or by the elements *to*, and *-ing* in (9b), (9c), (9e), and (9f), allow a separate negation. This tallies well with the truth-value property that should hold for all subject–predicate constructions. The same argument raises a problem in (9d), (9g), and (9h). These small clause predicates do not have the possibility of a separate negation. They can be denied but only by a negation placed on the matrix predicate. A strange, but unmistakable effect of this matrix negation is that precisely the bracketed part seems to be at issue, as shown in (11).

(11) I did not believe her to smile at me ≅ (I believed her not to smile at me

The same holds in (10b), where the matrix negation is realized. It seems more or less taken for granted in (10b) that carrots were on the menu and were consumed. The point of the denial is that neither these carrots, nor Mona Lisa herself, could qualify for the small clause predicate 'unwashed'. The sentential stress falls into the matrix predicate and within that matrix predicate it focuses the small clause predicate phrase. The denial, although placed on the matrix predicate, concerns the small clause predicate and takes the rest of the predicate for granted. This effect of matrix negation holds for the bracketed subparts in (10). An exception is the absolutive sentential adjunct in (9f): it requires a local negation, a negation element within the bracketed predicate; see (9f and 12).

(12) with Mona Lisa [– not smiling]

The small clause predicates can be negated and they require a subject that controls the phi-relations mentioned in (5), but the small clause predicates do not seem to contain an I^o projection.

Dummy Subjects and the Subject Configuration

All bracketed subparts in (9) select a DP subject that is positioned outside the (small clause) predicate. This can be demonstrated by means of so-called dummy subjects. Dummy subjects are selected as DP subjects by certain predicates, for example 'to snow' or 'to be obvious' as in (13).

(13a) it is snowing
(13b) it is obvious that Mona Lisa smiles

Dummy subjects are 3rd person singular pronouns that have no predicate assigned property (no theta role). Their message is 'instantiate this predicate here and now.' As (14) shows, dummy subjects do not allow a wh-variant.

(14a) *what is snowing?
(14b) *what is obvious that Mona Lisa smiles?

The predicates in (13) can appear as secondary predicates, as in (15). They continue to select the idiomatic dummy subject elements. The dummy element in (15a) clearly fits into a Spec.I, but less obviously in the other examples.

(15a) finite verb subject
it [– snows/is obvious that . . .]
(15b) infinitival raised subject-to-subject
it seems [– to snow/to be obvious that . . .]
(15c) infinitival raised subject-to-object
I believe it [– to snow/to be obvious that . . .]
(15d) infinitival accusative subject
I saw it [– snowing]
(15e) infinitival subject in for/to complement
I long for it [– to snow all day]
(15f) subjects in for/with absolutives
with it [– snowing] my day was made
(15g) small clause resultative subject
that smile made it [– snow/obvious that . . .]
(15h) small clause subject with 'as predicate'
I consider it [– as obvious that . . .]

The relevance of the dummy subjects is stressed in Rothstein (2001).

A dummy subject is a rather idiomatic phenomenon, but grammatical theory should preferably offer a configurational definition of subject that explains the parallel between I°-marked predicates and small clause predicates and that rules in dummy subjects. This is possible and leads to a few surprising reanalyses.

Koopman and Sportiche (1991) successfully reargued the predicate (VP) internal subject hypothesis. The lexical projection would already realize a propositional structure as indicated in diagram (16). For references and a survey of direct empirical arguments supporting the VP-internal subject hypothesis, see McCloskey (1997). Let now the merely lexical propositional structure VP as a whole be selected, for example by the I°. Then subject raising applies. See the transformational derivation of subjecthood by subject raising in (16).

(16)

Subjecthood by subject raising may hold for small clauses as well. A raising of the small clause subject into a matrix construction ends in a matrix object position *I [make her] [– happy]*. Fortunately, there are parallels between the subject and object position that may save the parallel between the I° subject and the small clause subject.

A quarter of human languages, according to an estimate in Bybee (1985: 30–31) based on a judicious 50-language sample, has verbal agreement for both structural arguments. The ambition of present-day configurationalism, which goes under the name Minimalism (Chomsky, 1995), aims to place subject as well as object in parallel configurations and outside the VP (explaining the object agreement).

The analysis of the object as a kind of small clause subject can be extended by analyzing affected objects as subjects of a resultative small clause (Postal, 1974; Hale and Keyser, 2002), as in (17).

(17) Mona Lisa cleaned the carrots ≅ Mona Lisa made the carrots clean

The use of intermediate subject configurations as in the causative analysis of resultative objects is manifest in serial languages (Déchaine, 1993).

Selectional Prominence of the Subject Argument

The configurational approach, especially in its 'minimalist' variant (Chomsky, 1995), stands for a considerable amount of phrase structure manipulation.

Within generative grammar, there are alternatives: Lexical Functional Grammar (Bresnan, 2001), Head Driven Phrase Structure Grammar (Sag and Wasow, 1999), and the proposal by Williams (2003) avoid the proliferation of phrasal structure and the associated system of argument to specifier movement. They all turn to the semantic properties that a predicate assigns to its arguments. These semantic properties are plausibly selected from a highly limited and prospectively universal set of options, so-called theta roles {agent, cause, affected object, affected person, goal, result, location} (Keenan and Comrie, 1977; cf. Sect. 1.3). There is a hierarchy among the theta roles. The agent theta role is selected for subject prominence in the unmarked case. Passive endings on the predicate may change the hierarchy effect, but only in a limited way. The usual subject theta role that is blocked for the passive-marked predicate, may either no longer be expressed at all, or it must take the form of an oblique adjunct 'by Mona Lisa' in (18). The new subject is either an impersonal dummy subject, or the argument that is next to the hierarchy in theta roles 'the visitor.'

(18) the visitor is smiled at by Mona Lisa

Since the selection of the subject argument follows from the hierarchy of theta roles, there is an option. Subject properties may follow from the subject configuration, as defined by the Extended Projection Principle, or they may follow more directly from theta role prominence. Antecedenthood for verbal agreement, reflexivity, or control may follow either from theta role prominence or from a configurational effect of that prominence.

A direct interpretation of subjecthood in terms of theta-role prominence offers a descriptive advantage. There is less configurational reanalysis of the string as in (20) above and all grammars with full or partial nonconfigurationality fit in easily. Part of this advantage is short-lived. The interpretative rules for syntactic function interact and lead to new complexity; see for instance Ristad (1993).

Typology

Survey of Properties

A more mundane, less theoretical, approach to the notion 'subject' has been tried out as well. Keenan

(1976a) lists 30 possible properties of subjects. There are all kinds of variation and there is no shared minimal subset of properties sufficiently theory-free that could be used as a straightforward observational check on subjecthood. Keenan's contention is the somewhat weaker claim that a DP in a clause must be the subject if it displays clearly more of these prototypical subject properties than a competitor. His main point is that surveys in comparative grammar, in which subjecthood figures highly, are by no means an exercise in global impressions. They are an empirically serious matter. Explaining the diversity of subject properties between languages is no less challenging than explaining the subject diversity within a specific language. Keenan divides his subject properties in three subsets: (1) semantic, (2) syntactic, and (3) pragmatic.

1. Keenan's semantic subject properties are the theta roles that a predicate may assign to its subject. Those roles are plausibly selected from a highly limited and prospectively universal set of options, as mentioned in the previous section. The semantic subject properties deal with theta hierarchy and its exceptions in so-called ergative and split-ergative languages.
2. Keenan's syntactic subject properties are the pronominal phi-features of the subject (number, person, gender) for verbal agreement, reflexives, and control (Schachter, 1976), illustrated in (5).
3. Keenan's pragmatic subject properties deal with the subject that must at the same time be definite, old information, and function as presumed or running discourse topic.

Pragmatic Subject Properties

A telling case of pragmatic subject properties is the subject in Sesotho (a Bantu language) as analyzed by Demuth (1989). The subject in the Sesotho system must be at the same time the definite presumed old information topic. Hence subject arguments cannot be questioned. Nevertheless and as usual, the agentive a role is preferred subject property. If one now would like to ask a 'who dunnit' question in Sesotho, the subject–predicate structure must be changed into the parallel construction 'by whom was it done.' And that is what happens; see (19) (Demuth, 1989: 67).

(19a)	*mang	o-pheh-ile	lijo?	
	who	sm-cook-prf	food?	
	(who cooked the food?)			
(19b)	lijo	li-pheh-il-o-e	ke	mang?
	food	sm-cook-prf-PASS-m	by	who?
	(the food was cooked by whom?)			

Subject-changing transformations succeed in maintaining the status of the subject as preordained old topic. The Sesotho case was brought up by Demuth in a discussion about the learnability of subject-changing transformations. As Demuth pointed out, the learnability of subject-changing transformations may relate to the discourse functions such transformations have. As a discourse device, passive is central in Sesotho. Sesotho children below the age of 3 show themselves as little masters in subject-changing constructions. By comparison, passive plays a more marginal role in English, and it is acquired later.

A comparable subject-changing issue appears in Keenan's (1976b) analysis of Malagasy, an Austronesian language on Madagascar. The subject in Malagasy must also function as an old information argument. Curiously, the subject is now the only argument that may appear as a relative pronoun. By consequence, if one would like to relativize an argument, it must be made subject and a subject-changing transformation is called for. Fortunately, and perhaps not by accident, Malagasy, like all Austronesian languages, is strong in subject-changing transformations.

Tagalog (Schachter, 1976) marks a single argument in each clause as the most prominent one. All other arguments have an oblique case. The prominent argument drops that oblique case and appears with a fixed single element *ang*. One might think of it as a topic marker. The obligatory prominence marking by *ang* co-occurs with a marking on the verb. This is reminiscent of the subject–verb relationship, but there is no verbal agreement by means of phi-features. The dependent marking on the verb indicates the theta role of the prominent argument. It is rather an indication of voice (active and various kinds of passive). The verb is in the initial position and the subsequent argument order is free without any obvious configurational structure. Schachter hesitates to welcome the prominent argument in Tagalog as the subject. The interesting reason is that all subject attributes that follow from the external position of the configurational subject are lacking. The single and grammatically marked prominent argument has no wide quantifier scope, is not the antecedent of reflexives, and is not the controlled argument in subordinates. The questioned argument, though, must have the prominent status and the relative clause is formed by dropping the prominent argument, because of its identity with the antecedent of the relative clause. See (20), adapted from Schachter (1976: 495).

(20) the woman will take some rice for the child out of the sack

subject marker – verb { <agent> <goal> <direction> <beneficent> }

(s/a)alis **ng** *babae* **ng** *bigas* **sa** *sako* **para-sa** *bata*

<agent> mag- ← ang

<goal> -s ← ang

<direction> -an ← ang

<beneficent> ipag- ← ang

- Only one of the arguments drops its (oblique) case for the topic marker *ang*.
- The verbal inflection subsequently expresses the theta role of the topic.
- The verb is in initial position. The linear order of the arguments is free.

Both Bantu Sesotho and Austronesian Tagalog have in principle a predicate-selected argument with unique prominence. At the same time, the prominent argument is bound to function as topic (old information argument) in Sesotho or as focus (new information argument) in Tagalog. Both systems combine the most prominent argument status with a topic or focus function. They succeed in doing so because of a high flexibility of the verbal paradigm. The selection of the prominent argument by the verb may target any standard argument, as a result of the variety of passive-like endings on the verb. These endings indicate whether the prominent argument is an agent, a beneficiary, a goal, or a location. Verbal systems with such a variety of passive-like endings are called applicative (Baker, 1988).

There are several languages that require a systematic marking of topic or focus. They may or may not collapse subject and topic marking. See Li and Thompson (1976). The parallel between propositional logic and clausal grammar is less clear in topic-oriented languages, since the topic need not be an argument of the predicate head at all. Predicates are no longer instantiated by means of argument prominence and the notion subject does not apply.

Conclusion

Subject–predicate relations appear in a variety of phrasal configurations and morphological markings see (9), (10). Moreover, they may be further associated consequences for reflexives, control of infinitival complements, coordinate structure reductions, subject-drop, switch reference phenomena, effects of quantifier scope, unstressed topic-hood requirements, long wh-movement restrictions, and so on. This constructional variety appears within the grammar of specific languages and it appears between them in comparative grammar. Yet it is a crucial property of human language to construct complex signs with a true/false value. Consequently, a theory of syntax that holds water should explain how this feat is arrived at by grammar and what its further distributional consequences are. Preferably, all subject–predicate variations in syntax should derive (naturally) from a single representation or a single descriptive device. Syntactic analysis may show how subjecthood is a privileged form of argument saturation and how that construction leads to the grammatical form for propositions with true/false values. No doubt such an ideal subject/predicate analysis will require syntactic tinkering for each new construction. Fortunately, the various syntactic workshops or programs in generative syntax offer all kinds of options. These alternatives are sometimes thinly veiled parallels, sometimes purposely incompatible. The syntacticians by their very ambition change the notion subject anyway. Initially, 'subject' was a plausible intuition about a few simple grammatical structures. On closer inspection, it turns into a somewhat unwieldy problem that legitimately involves the set up of the whole theory of syntax. Moreover, as far as the facts are concerned (and their reconstruction in grammatical theory), we are faced with chaos that continues to rise. This is as such of course not an objection to the notion subjecthood, nor is it a reason for dismay.

Definition

In a general sense, if an element α is subordinate to an element β, it is less prominent than β and usually α is dependent on β. In grammar, subordination is a pervasive phenomenon and occurs in many different guises. Consider the following example:

(1) I thought [$_{\text{Clause}}$ that [$_{\text{NP}}$ the endless storm] was frightening]]

Here, in the noun phrase *the endless storm* the head is the noun *storm*. It is preceded by the determinative *the*, which renders the phrase definite, while *endless* furnishes additional descriptive information about the head. In phrase structure, all elements are subordinate (although in different ways) to the head. The string *that the endless storm was frightening* is a subordinate clause. A defining characteristic of subordination (also called hypotaxis) is that the subordinate element or string is syntactically at a lower level in the overall structure than the element or string it is subordinate to. Thus in (1) *that the endless storm was frightening* is subordinate because it functions as the direct object of the verb *think*, which forms part of the main clause. In this article, I use the term 'subordination' in the narrower sense of clause linking, that is, as a grammatical phenomenon in which a clause is linked to another clause (or in some cases a phrasal head).

Markers of Subordination

When a clause is subordinate to another clause, the subordination is often marked. This can be done in a variety of ways.

Definition

In a general sense, if an element α is subordinate to an element β, it is less prominent than β and usually α is dependent on β. In grammar, subordination is a pervasive phenomenon and occurs in many different guises. Consider the following example:

(1) I thought [$_{\text{Clause}}$ that [$_{\text{NP}}$ the endless storm] was frightening]]

Here, in the noun phrase *the endless storm* the head is the noun *storm*. It is preceded by the determinative *the*, which renders the phrase definite, while *endless* furnishes additional descriptive information about the head. In phrase structure, all elements are subordinate (although in different ways) to the head. The string *that the endless storm was frightening* is a subordinate clause. A defining characteristic of subordination (also called hypotaxis) is that the subordinate element or string is syntactically at a lower level in the overall structure than the element or string it is subordinate to. Thus in (1) *that the endless storm was frightening* is subordinate because it functions as the direct object of the verb *think*, which forms part of the main clause. In this article, I use the term 'subordination' in the narrower sense of clause linking, that is, as a grammatical phenomenon in which a clause is linked to another clause (or in some cases a phrasal head).

Markers of Subordination

When a clause is subordinate to another clause, the subordination is often marked. This can be done in a variety of ways.

Subordinators

In the sentences that follow, the subordinate clauses (in italics) are linked to their host, the main clause, by an overt subordinator (in boldface):

(2) ***when*** *they arrived* all hell broke loose

(3) we liked the play ***because*** *the acting was superb*

(4) he never calls you ***although*** *he says he likes you very much*

(5) he claims ***that*** *the trains that go to Edinburgh are running on time*

(6) I don't know ***whether*** *they will cancel the appointment or not*

(7) the committee will decide ***if*** *you're suitable for this position*

(8) it is entirely appropriate ***for*** *you to comment on his management style*

The items *that, whether, if,* and *for* are often called complementizers because they introduce clauses that function as a complement to a verb or some other head. Some linguists have argued that a subset of items traditionally regarded as subordinators are prepositions; they then reserve the class of subordinators for only *that, whether, if,* and *for* (see, e.g., Huddleston, Pullum *et al.*, 2002).

Word Order

Subordination can also be signaled by changes in the canonical order of words as in (9), which shows English subject-auxiliary inversion:

(9) *had I known about her qualifications*, I would have offered her the job

The italicized clause is interpreted as carrying conditional meaning.

Compare (9) with (10), in which, this time, subject-auxiliary inversion is a feature of the main clause interrogative, whereas the subordinate interrogative clause in (11) has the expected word order of subject, auxiliary, and main verb:

(10) which books should I read?

(11) nobody seems to know *which books I should read*

In (11) the subordination is in actual fact jointly marked by the canonical word order of subject, auxiliary, and main verb, and the *wh*-phrase, which is associated with ('moved from') the direct object position following the verb *read*. An initial *wh*-phrase on its own is not enough to signal subordination, as (10) shows.

In Dutch, subordinate clauses have a different word order from main clauses. Compare (12) and (13):

(12) Willem heeft de kat vermoord
Willem has the cat murdered
'Willem has murdered the cat'

(13) ik denk dat Willem de kat heeft vermoord
I think that Willem the cat has murdered
'I think that Willem has murdered the cat'

Consider also the example in (14) from German, in which the predicative adjective phrase *krank* 'sick' would normally follow the verb in a main clause (*er ist krank*) (König and van der Auwera, 1988: 102).

(14) *weil* *er* *krank* *ist*, kann
because he sick is can
Fritz nicht mitkommen
Fred not come along
'because he is sick, Fred cannot come along'

Subordination is often signaled by desententialization (Lehmann, 1988), as in the following sentence in which the subject of the subordinate clause is missing (and, in addition, the verb form is nonfinite; this is discussed later).

(15) I want *to emigrate to Australia*

Verb Forms

Clauses may be finite, nonfinite, or verbless. Nonfinite and verbless clauses are always subordinate because they cannot stand on their own, as the following examples illustrate.

(16) *having taken a shower*, Fred was now ready to go out

(17) Sally had to walk home, *her car a wreck*

Clauses containing subjunctive verb forms are also always subordinate. Indeed, as Palmer (1987: 90) reminds us, "the term subjunctive is a translation into Latin from the Greek *hypotaktike*, which means 'subordinate'"; see also Lyons (1969: 312), who remarks that "for the traditional grammarian the subjunctive was the mood of subordination *par excellence*." In many languages, these verb forms are triggered by a verb in the main clause that expresses modal meanings such as factual remoteness, possibility, and unreality. Thus, in Spanish the verb *esperar* 'hope' takes a subordinate clause with a subjunctive verb:

(18) espero que el pueda venir
hope.I that he can.SUBJ come
'I hope that he can come'

Another way in which verb forms can signal subordination is through the phenomenon of switch

reference. Consider example (19) from Noonan (1985: 80–81), who noted that in Lango:

> [i]n ordinary subordinate clauses, both indicative and subjunctive, a verb inflected for third person must have a prefix indicating whether the subject of the subordinate clause is the same or different from the subject of the CTP [complement-taking predicate]. In the third person singular perfective, the prefix indicating same subject (SS, non-switch reference) is *è-*, and the unmarked prefix indicating a third person singular subject (which can be interpreted as switch reference) is *ó-*.

Thus, in (19) the subject of *ècégò* is *dákó* (non–switch reference), but in (20) the subject of *òcégò* cannot be *dákó* (switch reference).

(19) dákó òpòyò ní
woman remembered.3.SING.SUBJ COMP
ècégò dɔgólá
closed.3.SING.SS door
'the woman$_1$ remembered that she$_1$ closed the door'

(20) dákó òpòyò
woman remembered.3.SING.SUBJ
ní òcégò dɔgólá
COMP closed.3.SING.SUBJ door
'the woman$_1$ remembered that she$_2$ closed the door'

(Here SS indicates same subject.) This phenomemon is only possible in subordinate clauses.

Here are some Quechua examples from Cole (1982):

(21) Kitu-man chaya-shpa-mi
[Quito-ALL arrive-ADVLR.SS]-VAL
rijsi-ta riku-rka-ni
acquaintance-ACC see-PAST-1.SING
when I arrived in Quito, I saw a friend'

(22) ñuka Kitu-man chaya-jpi-mi
[I Quito-ALL arrive-ADVLR.DS]-VAL
rijsi riku-wa-rka
acquaintance see-OBJ.1-PAST.SUBJ.3
'when I arrived in Quito, a friend saw me'

(Here ALL indicates allative; ADVLR.SS indicates adverbializer, same subject; ADVLR.DS indicates adverbializer, different subject; and VAL indicates validator.) In these examples, the inflections on the verb at the end of the subordinate clause signal whether its subject is the same or different from that in the main clause.

Scope, Intonation, Semantic Linking, and Grammatical Category Dependence

Consider (23)

(23) I didn't go to the gallery because I wanted to meet Sue

This sentence is ambiguous. Under the first reading, the reason for my not going to the gallery was that I wanted to meet Sue in some other location. Under the second reading I **did** in fact go to the gallery, but the reason for my going there was not that I wanted to meet Sue but some other reason (we can continue the sentence in (23), saying *but because I wanted to see the pictures*). The difference between the two readings has to do with the scope of the negative element in the main clause. Under the second reading, it extends into the subordinate clause; under the first reading it does not. Notice that under the first reading there is an intonational break just before the subordinate clause, and there are thus two intonation contours for this complex sentence. For the second reading, there is just one contour. We thus see that a main and a subordinate clause, in addition to having overt markers of subordination, can be linked by the semantic notion of scope of negation.

Consider next a Russian example of intonational linking (Haiman and Thompson, 1984: 516):

(24) Alik ne xodit (PAUSE) spotykajas' (Russian)
Alik NEG walk stumbling

This sentence can be glossed in two ways, depending on whether there is a pause between *xodit* and *spotykajas*. If there is a pause, then (24) can be translated as 'Alik doesn't go because he stumbles' (i.e., with a subordinate clause), whereas without the pause it means 'Alik doesn't walk with a stumble.'

Semantic linking refers to meaning links that can be established between clauses, such as the mention of the same people or entities. The term grammatical category dependence (GCD; Van Valin, 1984) can be defined as a dependence between clauses in terms of voice, mood, tense, pronoun reference, and so on. Van Valin cites an example from Jacaltec (Craig, 1977):

(25) ch-in xubli an
NPAST-1.SING.ABS whistle 1P
x-Ø-(h)in-tx'ah-ni xil
PAST-3.ABS-1.SING.ERG-wash-SUFF CLASS
kape an
clothes 1P
'I washed the clothes whistling'

(Here NPAST indicates nonpast, ABS indicates absolutive, ERG indicates ergative, SUFF indicates suffix, and CLASS indicates classifier.) Van Valin (1984: 546) notes that

> the verb in the first clause must be in the neutral nonpast tense form, and the two clauses must have the same subject. The tense interpretation for the whole sentence is a function of the tense inflection of the verb in the second clause; there is therefore G[rammatical] C[ategory] dependence between the clauses.

Main Clause Phenomena

Emonds (1970, 1976) discusses a number of syntactic operations (transformations) that can only take place in root (i.e., main) clauses. Green (1976) dubbed these operations main clause phenomena (MCP). Among them are subject-auxiliary inversion (SAI), tag question formation (TQF), adverb preposing (AP), and topicalization (TOP). Here are a few illustrative examples (from Emonds, 1976: 21):

(26a) why weren't they cooperative? (SAI)
(26b) *she doesn't know why weren't they cooperative?

(27a) Mary had come, hadn't she? (TQF)
(27b) *Bill wanted to know whether Mary had come, hadn't she?

(28a) under no conditions may they leave the area. (AP)
(28b) *if under no conditions may they leave the area, how can they pay their debt?

(29a) these steps I used to sweep with a broom. (TOP)
(29b) *have I shown you the broom (that) these steps I used to sweep with?

Green (1976: 397) argues that, in fact, MCP can occur in subordinate clauses as well, provided certain conditions are met: "the embeddability of so-called MCP is influenced not only by syntactic forms and semantic functions, but also by pragmatic functions, by what a speaker is trying to do in using a particular syntactic form to express something." This view was endorsed by Bolinger (1977).

No Overt Marker of Subordination

Subordination can also be achieved without overt markers of subordination, as in the well-known cases of *that* – omission in English complement clauses:

(30) I believe (that) the monarchy won't survive for much longer

Here the string of words following *believe* can stand on its own, but should nevertheless be regarded as a subordinate clause by virtue of the fact that it functions as the direct object of *believe*.

Consider also:

(31) do that again and I'll punch you

Here the imperative clause seems to be coordinated with the clause *I'll punch you*, but it is interpreted as a conditional adjunct clause, that is, as *if you do that again*.

Circularity

Some linguists have pointed out (Haiman and Thompson, 1984; Thompson, 1985: 86) that one problem of using the phenomena discussed so far to identify subordination is that it may lead to circularity: "Why is this clause subordinate?" "Because it is introduced by a subordinator." "Why is it introduced by a subordinator?" "Because it is subordinate." Where possible, we therefore need to look for additional identifiers of subordination, as in (13), which combines the use of a subordinator with a change in word order. According to Palmer (1987: 97), it is the fact that the subordinate clause can follow or precede the main clause (compare also (2) and (3)) that distinguishes it from the coordinated clause, as in (32) and (33):

(32a) John came, although Mary stayed at home
(32b) although Mary stayed at home, John came

(33a) John came, but Mary stayed at home
(33b) *but Mary stayed at home, John came

However, this test does not always work, as when the element *for* is the subordinator:

(34) John laughed, for he was a fool
(35) *for he was a fool, John laughed

Palmer is forced to say that *for* is not a subordinator, even though it functions in the same way as the causal subordinator *because*.

The circularity problem has led some linguists to conclude that there is no meaningful grammatical notion of subordinate clause (Thompson, 1985: 86):

> '[S]ubordinate clause' is not a grammatical category at all. That is, there does not seem to be a single function or even a group of functions that we can think of this 'category' as having been designed, as it were, to serve. So the term 'subordination' seems to be at best a negative term which lumps together all deviations from some 'main clause' norm, which means that it treats as unified a set of facts which we think is not a single phenomenon. For these reasons, we have found it more fruitful to tease it apart into its component parts and try to determine what are the discourse motivations that underlie each of these components.

Some of these components have already been discussed (see also Haiman and Thompson, 1984: 511). For a discourse approach to subordination, see Matthiessen and Thompson (1988). For a typological approach see Cristofaro (2003: 2) where subordination is regarded as "a particular way to construe the cognitive relation between two events, such that one of them (which will be called the dependent event) lacks an autonomous profile, and is construed in the

perspective of the other event (which will be called the main event)."

Types of Subordinate Clause

Subordinate clauses can be classified as follows.

Content Clauses

The label 'content clause' was introduced by Otto Jespersen (1933) and was adopted in Huddleston, Pullum *et al.* (2002) to designate a type of clause that assumes a typical clause function, such as subject, direct object, and complement of a preposition. (Because content clauses often occur in NP positions, they have been called nominal clauses; cf. Quirk *et al.*, 1985: 1048.) They can be introduced by such elements as the complementizers *that, whether, if,* and *for* (examples are shown in (5)–(8)) or by *wh*-words (e.g., *I don't know* ***what*** *you mean*).

Comparative Clauses

As their name suggests, comparative clauses express a comparison between two terms. Here are some examples.

(36) these days Ben likes syntax more *than he did last year*

(37) the French are as mad *as the English are*

Relative Clauses

Relative clauses are used to postmodify noun heads.

(38) this is the camera *that we bought in America*.

(39) we invited Harry's father, *who loves barbecues*

The relative clause in (38) is a restrictive relative clause; it singles out a particular camera from the universe of discourse. In contrast, in (39) we have a nonrestrictive relative clause, so called because the clause does not serve to identify a unique entity in the universe of discourse.

Adjunct Clauses

Adjunct clauses furnish circumstantial information that is supplementary to the proposition expressed by the main clause. The subordinators that introduce adjunct clauses can signal a wide variety of meanings, among them 'time' (*when, while, since*), as in (2); 'reason' (*because since, as*), as in (3); 'concession' (*(al)though, (even) though*), as in (4); 'condition' (*if*), as in (40); 'result,' as in (41), and 'purpose,' as in (42) (this is by no means an exhaustive list of the meanings that can be expressed).

(40) *if you cook tomorrow* I will take you to the theatre

(41) the prisoners will be released *so that more space will be available*

(42) *in order that we can finalize the arrangements* all employees are requested to work overtime

Degrees of Subordination

Subordination is a matter of degree. First, clauses that are merely juxtaposed are paratactically linked, as in (43).

(43) Tim fell. He broke his arm.

Although there is an obvious semantic (causal) link between the first and second sentences in this example and co-reference is established through the use of the pronoun *he*, which may (but need not) refer back to Tim, grammatically neither sentence is subordinate to the other.

Consider next adjunct clauses, as in (40)–(42). These are clearly part of their containing sentences and subordinate in the sense of not being able to occur on their own and in furnishing nonessential information, but they are nonembedded. What this means is that they are not constituents (arguments) of some unit of the sentence, other than the sentence itself. In sentences containing adjunct clauses, more than one assertion is being made. Thus in (41) the assertions are *the prisoners will be released* and *more space will be available*. Another example of nonembedding is (25), which similarly displays dependence, but by virtue of grammatical category linking, not embedding. The combination of features [+dependent, −embedded] is termed 'cosubordination' in Van Valin (1984: 546), following Olson (1981). This is contrasted with subordination, which he regards as [+dependent, +embedded], and coordination, which can be characterized as [−dependent, −embedded]. Care should be taken with this terminology: some authors use the term 'hypotaxis' to mean what Van Valin called cosubordination (see, e.g., Matthiessen and Thompson, 1988: 283).

Matters are different for content clauses that function as complements in a sentence, for example, the *that*- clause in (5). These are said to be embedded, in this case in the verb phrase whose head requires a clausal complement. When embedding occurs, the complex sentence expresses just one assertion. In the case of (5): *X claims Y*.

Observe that it is necessary to recognize levels of embedding. Thus, the relative clause *that go to Edinburgh* in (5) is more deeply embedded than its

containing clause *that the trains that go to Edinburgh are running on time* because it is part of its subject NP. Levels of subordination can be signaled by intonation through intonational linking (see above). Consider the pair of sentences (45) and (46) (Bolinger, 1984: 410), as contrasted with (44):

(44) if you need it when you get there call me

(45) if you need it, when you get there call me

(46) if you need it when you get there, call me

Without any clues as to which intonation is intended, (44) is ambiguous; but with commas indicating intonational breaks, the *when* clause is either taken to be subordinate to *call me*, (45), or to *if you need it* (46). Notice also that the word *there* ends on a lower pitch in (46) than in (45).

Subordination versus Other Grammatical Notions

How can we distinguish subordination from other grammatical phenomena such as modification, complementation, and coordination?

Modification and complementation are both types of dependency and, as such, involve subordination. To clarify this, consider the noun phrase *the frightening storm that battered our house*. The head here is *storm*, and we will say that the element *the* and the string *that battered our house* are both dependent on the head and modify it; hence, they are subordinate to it in the wider sense. But only the relative clause is subordinate in the narrower sense used here, as involving a clause linked to a host.

Consider next (47) and (48):

(47) their discussion *of the problem* did nothing to cool tempers

(48) the fact *that he manipulated his audience* was beyond doubt

The subject noun phrase in (47) is headed by the noun *discussion*. It is preceded by the determiner *the* and followed by the prepositional phrase *of the problem*, which functions as a complement (cf. *they discussed the problem*). In (48), the *that* clause is said to be an appositive clause (in that it specifies the content of the head noun *fact*). It too functions as a nominal complement. In (47) there is subordination, in the narrow sense, in the shape of modification, whereas in (48) we have subordination in the wide **and** narrow senses of the term.

Subordination is distinguished from coordination. The latter links units at the same level, as in [*the vicar*] *and* [*the actress*], in which two noun phrases are coordinated and neither NP is subordinate to the other. Previously we came across an example in which a particular kind of coordination resembles subordination from a semantic point of view. Several linguists have argued that subordination and coordination cannot easily be distinguished. Thus, the Dutch grammarian Kruisinga (1932: 501) noted that "[i]t is perhaps hardly necessary to observe that the distinction between coordination and subordination is a relative one, allowing of intermediate cases." Huddleston (1984: 380, 382–383) makes similar comments. In Quirk *et al.* (1985: 927–928) the idea of gradience between subordination and coordination is worked out in detail. They posit six syntactic criteria (not ranked in order of importance) to characterize coordinating conjunctions. The more criteria a particular item conforms to, the more it is like a coordinating conjunction and the less it is like a subordinating conjunction. (Most of the examples that follow are from Quirk *et al.*, 1985: 921).

Criteria

1. The item can only occur at the beginning of a clause.

(49a) John plays the guitar, **and** his sister plays the piano

(49b) *John plays the guitar; his sister **and** plays the piano

2. In a sequence of coordinated clauses A and B, when B contains the item, B cannot precede A.

(50a) they are living in England, **or** they are spending a vacation there

(50b) ***or** they are spending a vacation there, they are living in England

3. A sequence of coordinating conjunctions is impossible, whereas subordinating conjunctions and conjuncts **can** combine with other linkers.

(51a) *he was unhappy about it, **and but** he did as he was told

(51b) he was unhappy about it, **and yet** he did as he was told

(51c) he asked to be transferred, **because** he was unhappy **and because** he saw no prospect of promotion

4. The item can link clauses but also predicates and other types of constituents.

(52a) I [may see you tomorrow] **or** [may phone later in the day]

(52b) *he [did not spend very much], **so that** [could afford a trip abroad]

Table 1 Co-ordination-subordination gradient

Criteria		*a*	*b*	*c*	*d*	*e*	*f*
Coordinators	*and, or*	+	+	+	+	+	+
	but	+	+	+	+	±	−
Conjuncts	*yet, so, nor*	+	+	×	+	−	−
	however, therefore	−	+	−	−	−	−
Subordinators	*for, so that*	+	+	+	−	−	−
	if, because	+	±	−	−	−	−

Source: Quirk *et al.* (1985).

5. The item can link subordinate clauses.

(53a) I wonder [whether you should go and see her] **or** [whether it is better to write to her]
(53b) *they didn't stay [although they were happy], **but** [although they were bored]

6. The item can link more than two clauses.

(54a) the battery may be disconnected, the connection may be loose, **or** the bulb may be faulty
(54b) *Kate watched television, **but** Gerry was reading, **but** Pete was singing

These criteria are then used to construct the matrix in Table 1 (see also Van Valin, 1984).

Subordination in Spoken Discourse

J Miller, University of Auckland, Auckland, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The distinction between main and subordinate clauses does not apply straightforwardly to unplanned spoken language. One difficulty is that it was developed with respect to sentences, but sentences are not useful in the analysis of unplanned speech. For detailed discussion, see Miller and Weinert (1998: Chap. 2) and Sornicola (1981), and for the opposing view, see Chafe (1994: 139–145). Another difficulty in subordination is that the distinction is based in part on syntactic and in part on discourse properties. Examples of the former are constructions that occur in main clauses but not in subordinate ones; examples of the latter are clauses that cannot stand on their own. When clauses such as *though she knew Bill might turn up* or *which she turned down* occur on their own as the first clauses in texts, the texts are incomplete and uninterpretable. Clauses such as *which she turned down* can constitute complete contributions to conversations, but not as the first utterance. Consider (1).

(1) Speaker A *so Jane had a proposal from Bill*
Speaker B *which she turned down*

Clauses such as *Eric wrote Jane a letter* occur as the very first contribution to a text or in the middle of a text. But a text consisting just of the clause *which she turned down* is incomplete in syntax and meaning.

Main and Subordinate Clauses in Written Language

Syntactic Subordination

In written texts, main and subordinate clauses are syntactically quite distinguishable. Main clauses are never embedded; certain types of subordinate clause – restrictive relative clauses and complement clauses – are always embedded. In (2a) the restrictive relative clause, in bold, is part of the phrase *the book you lent me*; in (2b) the complement clause is part of the verb phrase *heard that you had retired*; in (2c) the complement clause is part of the noun phrase *the rumor that you had retired*.

(2a) I haven't finished the book **you lent me**
(2b) We heard **that you had retired**
(2c) We heard the rumor **that you had retired**

Main clauses allow an extensive range of constructions: They can be declarative as in (3a), interrogative (as in 3b), imperative as in (3c); they allow tag questions as in (4a), subject-verb inversion with negatives as in (4b), and the fronting of prepositional phrases as in (4c).

(3a) Bill arrived unannounced
(3b) Did Bill arrive unannounced?
(3c) Arrive unannounced!

(4a) Bill arrived unannounced, **didn't he?**
(4b) **Never has Bill** arrived unannounced
(4c) **Into the house came Bill**, unannounced

Subordinate clauses do not allow the same range of constructions as main clauses. Relative clauses, complement clauses, and adverbial clauses all exclude, for example, interrogative syntax.

(5a) *I hated the book **which did you say you liked it?**
(5b) *She said **that did they find a suitable house?**
(5c) ***If were they at the party**, I didn't see them

Even in written English some types of subordinate clause are more subordinate than others; the negative-inversion construction in (4b) is excluded from relative clauses and adverbial clauses but allowed in complement clauses – *The inspectors reported that never had they been so astonished*.

Discourse Subordination

A second type of subordination relates to discourse and is signaled by the use of anaphoric pronouns, ellipsis, and conjunctions. Consider the anaphoric pronouns in (6), in bold. *They* refers back to *the keen students*, *he* refers back to *the professor*, and *then* refers to the time at which the assignment was submitted. The clauses with anaphoric pronouns can only be interpreted with respect to the preceding clauses and are discourse subordinate.

(6) The keen students decided to submit the assignment to the professor on Thursday. **They** thought **he** would **then** allow **them** to go home. **He** didn't.

(7) illustrates the linking of clauses with conjunctions (shown in bold).

(7) The workers demanded better conditions and went on strike. **Consequently** the management locked the workers out. **However**, the workers summoned reinforcements and picketed the factory.

The clauses with *Consequently* and *However* have to be interpreted with respect to the preceding clauses and are discourse subordinate.

Main and Subordinate Clauses in Unplanned Speech

Unplanned spoken English (and other languages) does not permit such a clear-cut distinction between main and subordinate clauses. Speakers use a higher proportion of main clauses; clauses that look like subordinate clauses function as main clauses; clauses that look like subordinate clauses have the word orders typical of main clauses in writing; unplanned speech contains combinations of clauses that are not related as main clause–subordinate clause.

Main Clauses in Speech; Subordinate Clauses in Writing

(8a–c) demonstrate the use of main clauses in English and French for purposes that would require a subordinate clause in writing.

(8a) OK we install it there's no guarantee it'll work
(8b) je serais à ta place je partirais tout de suite [French]
I would-be in your place I would-leave immediately
(8c) I saw him I didn't speak to him though

(8a), with the particle *OK* followed by the clause *we install it* has the force of the written version *Even if we install it, there's no guarantee it'll work*. The first main clause does the work of a conditional-concession clause.

In (8b) the connection between the two main clauses is signaled by the Imperfect Future forms of the verb *serais* and *partirais*. The first expresses a remote condition, and in writing would be *Si j'étais* 'If I were.' The second conveys the resulting state of affairs. Otherwise, each clause is syntactically and semantically complete.

In (8c) a main clause conveys a concession – *I didn't speak to him though*. The clause comes second but *though* is not a subordinating conjunction. (Compare *although I didn't speak to him*.)

Adverbial Clauses Functioning as Main Clauses

(9a–c) show apparent adverbial clauses of reason, condition, and time functioning as main clauses.

(9a) Speaker A: they go to X now do they not the school?
Speaker B: yeah cos it's indoors
(9b) Right if you listen to me carefully, you are going to be asked questions about Y
(9c) I was bringing in the shopping when the dog jumped up and knocked the bag of bottles out of my hand

(9a) is from conversation. Speaker B produces an apparent adverbial clause of reason modifying the clause which would be the answer to A's question: *they go to X*. Of course Speaker A could have uttered the whole chunk *they go to X cos it's indoors*. (The reference is to a swimming pool.)

Such *cos/because* clauses function almost like main clauses. They allow tag questions – *cos it's indoors isn't it*, adverb fronting – *everyone had a laugh cos into the pool jumped a dog*, and negative inversion – *cos never had the pool been so busy*. In contrast, adverbial clauses of reason preceding main clauses have restricted syntax; for instance, adverb fronting is not possible: **because into the pool jumped a dog, everyone scrambled out*.

(9b) is from an interview in a police station. The *if* clause is not an adverbial clause of condition but a frequently used device for giving instructions. It is widely used by medical staff talking to patients, for example. Although functioning as an imperative main clause, it has the same restricted syntax as ordinary adverbial clauses.

In (9c) *when the dog jumped up* looks like an adverbial clause of time. However, it allows main-clause constructions (adverb fronting – *when into the pool jumped the dog*, tag questions – *when the dog knocked the stuff out my my hand, didn't it?*) and functions like a main clause. *When* adverbial clauses typically describe an event preceding the event described by the main clause: *when the dog jumped up I dropped all the shopping*. In (9c) it describes the event following. *When* is not a subordinating conjunction but coordinates the clauses.

Clause Combinations and Unintegrated Syntax

Speakers and writers combine clauses but in different fashion. In edited writing, clauses are integrated. Unplanned speech has *Sue likes crosswords and Bill hates them* or even *Sue likes crosswords* [pause] *Bill hates them*. One complete clause follows another complete clause. *And* is not necessary; the connection is the anaphoric link between *them* and *crosswords*.

Planned writing might have *Sue likes, and Bill hates, crosswords*, deriving from *Sue likes crosswords* and *Bill hates crosswords*. The 'recipe' is: take *Sue likes* from the first clause; insert a comma; take *Bill hates* from the second clause; put in a comma; take the two instances of *crosswords*, insert one after the second comma and delete the other. The integrating of the clauses is clear.

In writing, relative clauses are integrated into noun phrases. Suppose we have the noun phrase *some eggs* and the clause *you're not sure about the age of the eggs*. To integrate the clause into the noun phrase, replace *of the eggs* with *whose*, substitute *whose* for *the*, and move *about whose age* to the beginning of the clause. This produces the written structure *some eggs about whose age you're not sure*. What was produced in speech (during a television program on cookery) was *some eggs you're not sure about their age*. The clause *you're not sure about their age* is discourse-subordinate; *their* refers back to, and the clause modifies, *some eggs*. Whether the clause is a relative clause is a moot question.

A number of constructions contain clauses that are not obviously related as main clause and subordinate clause. Consider the examples in (10).

(10a) what you do is put a spile into the barrel
(10b) I'll just give the mixture a little stir because what happens is things tend to settle a bit
(10c) What we're doing we're hanging them up to dry

(10a) is a classic WH cleft. The free relative clause *what you do* is the subject of *is*. The complement of *is* is the nonfinite clause *put a spile into the barrel*. This clause is well integrated into the overall construction; it has no subject noun phrase and no tense, person, or number, just the bare verb stem. (10b) is the WH cleft typical of unplanned speech. The complement of *is* is a complete clause with overt subject *things* and a verb *tend* with tense, person, and number. However, the tense of *tend* is controlled by the tense of *happens*; that is, the clause is not entirely free. It can stand on its own, whereas *what happens is* requires, and has, a complement; the complement is simply not integrated into the general construction.

In (10c) the clause *what we're doing* and the second clause, *we're hanging them up to dry*, are merely juxtaposed. The second clause is not the complement of *is*, has its own subject noun phrase, and has a verb marked for tense, person, and number. As in (10b), the tense and aspect of *'re doing* controls the tense and aspect of *'re hanging*, and *what we're doing* is incomplete because *what* points forward to something, which has to be specified. The second clause specifies the something. *Subordination* is not the appropriate term for this loose connection but rather *cosubordination* (Van Valin and La Polla, 1997) is.

Finally we turn to (11).

(11) Everyone knows Helen Liddell how hard she works

The main clause is *Everyone knows Helen Liddell*. The clause *how hard she works* cannot be the direct object of *knows*, because verbs have one direct object and the direct object of *knows* is *Helen Liddell*. The *how* clause is connected with the main clause in that *she* is co-referential with *Helen Liddell*. This type of referential linkage, however, does not demonstrate that the *how* clause is embedded in the main clause, because referential linkage operates across sentence boundaries in written language.

Conclusion

Constructions analogous to those in (8) through (11) are found in unplanned speech in other languages, along with other clauses. Heath (1985: 104) talks of the choppy, fragmented character of the syntax in spoken data from an Australian Aboriginal language, Ngandi, and warns against forcing the data into the mold of clear-cut sentences and clauses. His warning is as necessary in 2004 as it was in 1985.

Subtitling

Y Gambier, University of Turku, Turku, Finland

© 2006 Elsevier Ltd. All rights reserved.

Language transfer for television, cinema, and video receives increasing attention. More than a problem, audiovisual translation (AVT) is a solution and an asset in multilingual exchanges – both cultural and informational exchanges.

There are three fundamental issues in the AVT field, namely, the relationship between verbal output and pictures and soundtrack, between a foreign language/culture and the target language(s)/culture(s), and finally between the spoken code and the written one.

The Nature of Subtitling

Several forms of AV language transfer exist. The best known are dubbing, subtitling, voice-over, and live interpreting. However, other forms also are used on special occasions, such as surtitling in certain opera houses and theaters, or for specific target groups, such as audio description for the blind and visually impaired.

Subtitling is an overt type of translation: the original version can be heard at the same time as the viewer reads the one or two lines, thus enabling criticism from anybody with the slightest knowledge of the source language.

Subtitles are condensed translations of original speech, which appear as lines of text usually positioned toward the bottom of the screen or vertically on the side of the screen. They can be either interlingual (or open caption) from one language or several in the case of multilingual films, to another, sometimes to two other languages (bilingual subtitling as occurs in Finland, Belgium, and Israel), or intralingual (or closed caption), within the same language, e.g., for the deaf and hard-of-hearing, and sometimes to help migrants, for instance, to learn or to improve their command of their new language. For example, TV5 in French-speaking countries broadcasts films with French subtitles, BBC4 in Great Britain with English subtitles, STV4 in Sweden with Swedish subtitles, etc. Different tools are available for this task. These include Teletext, in widespread use, and DVB format (Digital Video Broadcasting), a more advanced form of closed caption which requires a decoder external to the television set. Closed subtitling is selected by the individual viewer on a remote-control unit.

Open subtitles when used are not optional: They are a physical part of the film or the television picture. They can sometimes be transmitted separately, for instance, at festival screenings.

In addition to the two main types of subtitling, we can also mention

- Reduced subtitling, dealing with news or live events, such as sport programs. The purpose of this special variant of subtitling is not to give a full translation of what is being said, but to provide a summary, a shortened or quick commentary.
- Live or real-time subtitling, used in various types of interviews, debates, or special events, such as President Clinton's hearing in the U.S. Supreme Court for sexual harassment in 1998. But of course writing at the same speed as normal speech is not easy, even with special 'chord keyboards' that allow the typist to press two or more keys at the same time, i.e., to key syllables and even whole words instead of only individual letters. Moreover, the differences between spoken and written language should be taken into account, so that the written version is slightly more formal and condensed. Subtitlers, just like conference interpreters, must first understand what the speaker intends to say. This makes great demands on their power of analysis and memory of the meaning expressed orally.

The Evolution of Subtitling

Subtitles evolve out of intertitles, which were used until the 1920s as devices to convey film dialogue, explanations, or commentaries to the audience. Text was printed on paper or cardboard, filmed, and inserted between sequences. Like modern subtitles, these intertitles attempted to communicate a complete idea, and punctuation was used to facilitate the reading. In the era of silent films, the translation of the original intertitles was a relatively easy task – the source text being already in a written condensed form.

The arrival of the 'talkies' films from 1927 onward led to the gradual disappearance of intertitles, and the problem of language transfer in the film industry took on new dimensions. The major production companies were already highly dependent on selling their films abroad. At first, several versions of the same film were shot in different languages using different teams of actors. Then, filmmakers found a different solution by letting other actors speak the parts translated into the target language and replacing the original soundtrack by the new recording: Thus, dubbing was born. However, subtitling also developed further during the same period.

Different methods were tried, from the mechanical and thermal methods to the photochemical method, the optical method, and, at the end of the 1980s, laser burning. Since the 1980s, the process of planning, preparing, and generating subtitles, for cinema and television, has become more and more computerized. Fully electronic systems enable translation, editing, and time-coding to be done at the same computer-based workstation. In 1997, a Windows-based subtitling unit was launched, providing not only all the technical functions but also linguistic aids (built-in dictionaries, spelling and grammar checkers, etc.).

The Process of Subtitling

The Constraining Factors

A certain number of medium-defined constraining factors must be taken into consideration to get 'good' subtitling.

Temporal Constraints Reading speed, undoubtedly the main limiting factor, is usually slower than talking speed. But this is subject to great variation. Reading speeds can be affected by the viewers' education, age, reading habits, and attitude to the topics of programs or films. The complexity of the linguistic and factual information of the subtitles can also affect readability. For instance, high lexical density, condensation with no redundancy, and too few cohesive devices call for added exposure time of the subtitles and slow down the reading process. Furthermore, it has been assumed that identical subtitles are easier to read from a cinema screen than from a television (TV) set or a VHS (Video Home System) recording. The size of the screen, the differences in resolution (pixels), and the frame rate (24 frames per second at the cinema; 25 on television (PAL and SECAM systems), analogue video productions, and DVD; 30 frames/second in the NTSC–TV system in the United States, South America, and Japan) might explain the differences, or at least the feeling that you need about 30% more time to read subtitles on a TV screen than on a big cinema screen. Another feature affecting readability is the genre of AV products. You can anticipate the story and guess the dialogue in a love affair, while you need all the information in a documentary on oil rigs. Because of all these parameters, it is difficult to standardize presentation rates, even though subtitlers must take into account the different target audiences that could be exposed to their work. The rule of thumb on subtitle speeds is that the number of subtitles in an average 90-minute film is 900 for the cinema version, 750 for the video version, and 650 for the television version.

Spatial and Visual Constraints News, current affairs programs, interviews, and many documentaries are often packed with information, and faces often dominate the screen. The subtitles should not then interfere with the composition of the picture and should not compete for the viewers' attention. Therefore, a few questions must be asked here: What is the possible length of the line? How many lines can be used? What should be the positioning and duration of the subtitles? Although precise timing is usually defined in terms of subtitle-speech synchronization, eye-movement studies have proved that subtitling that does not pay attention to shot changes makes viewers start rereading the subtitles and could cause perceptual confusion.

In addition to these constraints, there are two other important factors: translation policy and working conditions. Translation policy here means conventions, norms, and directives made explicit by the broadcaster, the subtitling company, or the film producer or distributor: how do you deal with swearwords and taboos, dialectal and sociolectal features of speech, registers (especially in the shift from spoken to written code), or songs? Translation policy is related to the role played overtly or not by the company: For instance, a public TV channel may accept a social and linguistic role (promoting certain standards), while a commercial TV channel would consider only audience ratings. To facilitate the translation assignment, a company might buy programs and also require a master list (script of a TV show or a film containing a shortened text of the actors' lines in the original or a pivot language, usually English), or a post-production list (text prepared or edited after the shooting, with descriptions of the action and language notes), or a dialogue list (in addition to the dialogue, it offers information on the implicit sociocultural allusions and connotations, explains punning and word play, gives correct spelling of proper names, elucidates the meaning of colloquialisms and dialectalisms, etc.). All these data and information help subtitlers because usually their working conditions – tight deadlines, low wages – are not optimal for researching documentation, or terminology, and also because, as mentioned above, subtitles are always challenged.

To conclude this discussion of the constraining factors, I would like to stress the multi-semiotic dimension of an AV production. There are four main sets of signs:

1. the verbal auditory signs, including mainly dialogue and background voices, with their intonation, prosody, delivery, etc.
2. the nonverbal auditory signs, comprising natural sounds, laughs, sound effects, music.
3. the verbal visual signs, made up of the subtitles and different kinds of captions: shop and road signs, street names, newspaper headlines, letters, menus, placards, posters, etc.
4. the nonverbal visual signs, including composition of the image, takes with different camera positions and movements, types of shots, lighting, editing (overall rhythm), use of colors, clothing, body language, gestures, facial expressions, proxemics, etc.

The relationship between all these semiotic systems is complex. In a situation comedy (1) is dominant; a musical deals mainly with (2); (1) prevails in a 'talking head' program; a horror or adventure film uses especially (4), etc. In this relationship, the signs can be complementary, in contradiction (i.e., a gesture (4) opposed to what is being said (1)), equivalent, redundant, etc.

Whatever the case, the appropriate subtitling must appear in synchronicity with AV elements – synchronicity between auditory signs and subtitle content, between image and layout of the subtitles, and between camera takes and subtitle rates.

Stages of the Work

In some companies and countries, subtitling is atomized between a translator who phrases the subtitles and a technician, with little or no knowledge of the source language, who does the spotting or cueing (defining the in and out times of individual subtitle) and feeds the translated subtitles into the computer. In such a division of labor, the rate of errors is high. But, in most cases, thanks to technology, the work is now done by the same person who breaks up the dialogue into short sentences and formulates the subtitles, the times being marked in hours, minutes, seconds, and frames. Subtitlers work at a personal computer connected to a video recorder, a time coder, and a keyer to generate the subtitles on the screen.

When scanning a film or copying a video, it is important that the copied version on video has the same time code as the original supplied by the client. Because of the different frame rate, in a 100-minute film the discrepancy between film and video amounts to 4 minutes. Therefore, one frame/second has to be added during the scanning process. Once an in-house master copy with an identical time code has been made and the subtitler has watched the film or TV program (with the dialogue list), the actual translation starts as does the cueing – one of the most important stages of the work, striking a balance between the rhythm of the AV production, the speech rhythm of the characters, and the viewers' reading rhythm and expectations. When the subtitles are completed, they are, ideally, proofread, and then edited (checking how precisely dialogues and subtitles match, how each line fits the context, whether the subtitles are easy to read, and then making the necessary changes). Next, they are converted for the laser engraving (for film material) or recorded for broadcasting or distribution. If there is no dialogue list, the subtitlers must work from the screen, relying on their eyes and ears. In this case, the decoding effort can be heavy and difficult. These questions need to be addressed in many situations: Who commissions the translation? How are the subtitlers selected? Who does the proofreading? Who controls the final output?

Strategies

When subtitlers have decided how to interpret the dialogue and what to translate, taking into account all the AV elements, they segment the utterances into subtitles, keeping in mind target-audience reading abilities. To find target-language equivalents and correct and appropriate subtitles adapted to the recipients, they have different strategies at their disposal:

Reducing: Reduction can be either partial or total.

- *Condensing (*or *compressing)*. Redundant occurrences and oral features can be left out; numbers can be given by a figure and not in letters; fewer letters can be used (e.g., 'huge,' instead of 'immense' – h/u are smaller than m); paraphrasing allows a concise sentence, etc.
- *Elimination*. Parts of the contents in a verbose scene or a fast speech can be cut, especially when they are supported by AV information.
- *Omitting*. Repetitions, reiterations (e.g., of greetings), tautologies, tag questions, terms of address can be left out.

These three strategies are often combined. For example, condensing frequently implies omitting. The volume and level of reduction vary according to the pace of the original, the number of cuts, the complexity of the text, the genre, and the medium: the amount of reduction is more limited in documentaries than in fiction, and more limited in TV news than in video recordings.

Simplifying the syntax (complex sentences with embedded propositions can be transformed into two or three simple sentences; transposition can be used, e.g., a phrase can be changed into nominalization; active constructions can be used instead of passive

ones; a proper name can be substituted by a pronoun; a series of questions and answers can be replaced by a statement, etc.). And *simplifying the vocabulary* (use of hyperonym; shift in the lexical register; leveling out or neutralization of marked words; substitution of a brand name by a generic term, etc.).

Summarizing: Two or three cues of a dialogue can be merged into a single line; dislocation can be used, etc.

Expansion, including *explicitation,* adding information to explicate a term or a meaning, e.g.,

Do you go to Madame Tussaud?
Vas-tu au musée de cire?
Do you go to the wax museum?

and *adaptation* or dynamic equivalence, condensation, naturalization, e.g.,

They married right after graduation
Ils se sont mariés après l'examen
They married after the examination

e.g.,

After graduation
Après les oraux
After the oral exams.

All these strategies are interrelated, e.g., paraphrasing going hand in hand with simplifying or sometimes expansion; nominalization with omitting; simplifying with expansion, etc. In all cases, the subtitlers must select what to keep, what to change, and what is relevant and necessary in a given context.

For specific problems, such as translating cultural items, wordplay, idioms, and metaphors, other strategies could be added (borrowing, literal translation, calques, etc.). But the general rule is always readability: The appropriate amount of condensation, omissions, and so on does not depend only on linguistic elements; they should facilitate comprehension and not make subtitles more difficult to process.

Design

To ensure legibility of fixed subtitles, a number of problems, to be discussed below, need to be overcome. However, so far, there is no unified code of subtitling practices that would establish a clearly outlined standard for high-quality subtitles. What follows mixes different actual practices, and the values given are a rough mean value.

Positioning Subtitles are usually at the bottom of the screen; in certain cases, they can be placed in the upper part because important visual information or original captions are displayed at the bottom. In cinema screening, they are presented centrally, while on TV they can be centered or left aligned, or right-justified for languages such as Arabic. The following is an example of left-justification:

We all hope
you are feeling much better.

Next, an example of center-justification:

We all hope you are
feeling much better.

And an example of right-justification:

We all hope you are feeling
much better.

Legibility and Duration The maximum number of characters (letters and spaces) per subtitle line ranges between 30 and 40 characters, depending on the standard (cinema or television) and the target audience (children, fast-reading young people, the educated, the hard of hearing, the elderly with slower reaction time, etc.). Beyond 40 characters, the font size requires a reduction, making legibility more difficult.

Subtitles for the cinema are white; for television, they can be presented in different colors (white, yellow, etc.) and sometimes against a dark strip (grey or black). In intralingual subtitles, different colors are used to identify characters, or noises. Typefaces and letter spacing also affect legibility.

The average reading speed of TV viewers is between 2 1/2 and 3 words per second or 90–180 words per minute. Therefore, a full two-liner with 14–16 words should remain for a maximum time of approximately 5 1/2 seconds; a full one-liner should be kept for about 3 seconds, and 1 1/2 lines for about 4 seconds. The minimum duration for a simple-word subtitle is 1 1/2 seconds. Film subtitles require about 30% less reading time. The problem for cinema and TV is keeping subtitles on the screen long enough to allow reading time but not too long, to prevent re-reading.

Subtitles appear up to one-quarter of a second after the start of speech so that the viewer has time to identify the speaker, but this rule does not usually apply to monologues or narrative sequences. In such cases, the in-time of the subtitle is synchronized with the onset of the utterance.

Subtitles should not be left on the screen for more than 2 seconds after the end of a dialogue or a monologue. Finally, they should disappear at least four frames before a cut or a shot change, and be inserted no earlier than three frames after the cut to avoid a flashing effect.

Number of Lines Where the amount of text and the time available make a two-liner the better option, the upper line is usually shorter than the lower one.

Indeed, there is no simple answer to the question of how to divide up the text between the two lines, but what is important, for reasons of readability, is that lines should be divided, as far as possible, according to sense blocks, i.e., words connected by semantics, logic, or grammar should be written in the same line.

When a sentence must be carried over into two or more subtitles, usage differs from country to country and from one television channel to another. In some places, a dash can be used at the end of an unfinished subtitle and at the beginning of the next. In other places, the only indication is the absence of a full stop and the use of a small letter at the beginning of the second subtitle.

At least four frames are inserted between two consecutive subtitles. This time break is necessary to signal to the brain the disappearance of one subtitle and the appearance of another.

Linking subtitles and line breaks have been investigated empirically but with a limited volume of data, and because several factors are involved, results are unclear.

Punctuation and Other Conventions The overriding principle concerning punctuation, italics, capitals, abbreviations, etc., in subtitles is that they should help viewers understand the meaning and avoid any form of irritation (viewers are unable to go back and reread what they have missed). Commas, colons, semicolons, exclamation marks, uppercase letters, etc., are used in different ways and with different frequency in different companies. Thus, suspension dots can indicate hesitation, interruption and/or sentence continuation.

To test the suitability of all the practices mentioned in this section, research studies and surveys should be carried out more systematically.

Quality

To sum up, we can claim that different factors influence the quality of the subtitlers' work.

The features of the subtitles. The accuracy of the subtitles must be considered along with the sound and the images. Two sets of characteristics help to produce optimum results: the scripto-temporal features that define legibility (types of font, positioning, number of characters per line, duration on the screen, etc.) and the textual features that define readability (subtitles as semantic, syntactic, and idiomatic units; application of different strategies; obligation to select the appropriate register; use of relevant punctuation, etc.). All these features are strongly target-oriented, taking into consideration the reading speed rates and cognitive efforts of the audience.

The organizational factors. Translators are not the only experts in AV communication. Producers, distributors, broadcasting decision-makers, etc., also have their own interests and expectations. They determine the working conditions of the translators (access to a dialogue list, time pressure, technical tools, and credit and copyright, etc.). Quality is the key word in subtitling and the result of a cooperation that should acknowledge the role and the place of AVT in cinema, television, and video.

The sociocultural implications of the translation. Another factor that could also change the perception of subtitling is its influence on language learning and reading skills. There is as yet no study correlating illiteracy and reading subtitles, but the fact remains that we are reading television. Where subtitling is the dominant form of AVT, a viewer watching all the programs would read more than 200 novels of 300 pages per year. On the other hand, a few studies have already shown that subtitling can improve the learning of phonemes, intonation, accent, and expressions in a foreign language. Furthermore, some research has emphasized the potential importance of subtitles in the language education of the deaf and hard-of-hearing.

Another implication is the linguistic role of the AV media. At different times, literature, the school, or the printing press were the institutions where language norms were established and disseminated. Television and the Internet are beginning to fulfill that function. By blurring the borders between the written and the oral, subtitling compels us to question what norm(s) are to be used and to what extent oral features change traditional views of the written language.

Another linguistic-political implication of subtitling could also be to strengthen the dominance of English, as a pivot language facilitating international program exchanges and as a way to display more and more anglicisms and English interference.

Cinema, video, public television channels, satellite television, and commercial television channels do not play an absolutely identical part in all these implications.

Subtraction

L Bauer, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Morphological subtraction includes a number of phenomena which may be viewed as taxonomically distinct. Four of these are treated briefly below. Subtraction has long been a problem for theoretical linguistics, which has preferred to deal with forms rather than omitted material, as well as for psycholinguistics, where the processes involved in subtraction have not been clear. However, recent approaches such as prosodic morphology show signs of being able to incorporate the phenomenon into standard descriptions. Subtraction has to be distinguished in principle from purely phonological sandhi phenomena in which individual segments may be deleted at morphological or syntactic boundaries (e.g., in Tunica, an unstressed vowel at the end of a morph is deleted before a morph-initial glottal stop, so that from *ʔaka* 'enter' + *ʔuhki* 'he did' we derive *ʔakʔuhki* 'he entered' – Haas 1946), though in practice this distinction may be difficult to apply consistently.

Subtractive Morph

A subtractive morph is the label given in structuralist studies to instances where the removal of a particular piece of form has an effect parallel to the addition of morphological form elsewhere in the language. A typical case can be found from French adjectival marking.

French adjectives agree with the noun they modify for number and gender. Here we are concerned with gender agreement, and will accordingly just use singular forms (though the plural forms in the instances shown below are not different in isolation). The set of

Subtraction

L Bauer, Victoria University of Wellington, Wellington, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Morphological subtraction includes a number of phenomena which may be viewed as taxonomically distinct. Four of these are treated briefly below. Subtraction has long been a problem for theoretical linguistics, which has preferred to deal with forms rather than omitted material, as well as for psycholinguistics, where the processes involved in subtraction have not been clear. However, recent approaches such as prosodic morphology show signs of being able to incorporate the phenomenon into standard descriptions. Subtraction has to be distinguished in principle from purely phonological sandhi phenomena in which individual segments may be deleted at morphological or syntactic boundaries (e.g., in Tunica, an unstressed vowel at the end of a morph is deleted before a morph-initial glottal stop, so that from *ʔaka* 'enter' + *ʔuhki* 'he did' we derive *ʔakʔuhki* 'he entered' – Haas 1946), though in practice this distinction may be difficult to apply consistently.

Subtractive Morph

A subtractive morph is the label given in structuralist studies to instances where the removal of a particular piece of form has an effect parallel to the addition of morphological form elsewhere in the language. A typical case can be found from French adjectival marking.

French adjectives agree with the noun they modify for number and gender. Here we are concerned with gender agreement, and will accordingly just use singular forms (though the plural forms in the instances shown below are not different in isolation). The set of

adjectives in (1) shows that there is some regularity in the relationship between the masculine and the feminine form (although there are other adjectives which do not show agreement in the same way).

(1) Gloss	Masculine	Feminine
'bad'	movɛ	movɛz
'big'	gʁɑ̃	gʁɑ̃d
'cool'	fʁɛ	fʁɛʃ
'deep'	pʁofɔ̃	pʁofɔ̃d
'false'	fo	fos
'gentle'	du	dus
'happy'	œʁø	œrøz
'long'	lɔ̃	lɔ̃g
'naughty'	meʃɑ̃	meʃɑ̃t
'small'	pəti	pətit
'white'	blɑ̃	blɑ̃ʃ

The point about the examples in (1) is that it is not possible to predict the final consonant in the feminine form from the masculine form; it is, however, possible to predict the masculine form from the feminine form – delete the last consonant. This subtractive analysis has to be seen against the background of a system where the derivation of the feminine form from the masculine form is additive in the written language (which represents a historically earlier form of French). There is some evidence (Fink, 1985) that French L1 speakers do not use the rule of subtraction to create masculine forms of adjectives, and such psycholinguistic counter-indications to the most economical analysis bedevil analyses based on subtraction (see Bauer, 1997: 479 on Maori passive endings). Really good examples of subtraction of this kind are correspondingly hard to find, and most of those in the literature seem to be synchronically dubious or of a rather different nature.

Another example comes from Tohono O'odham (formerly called Papago), where the perfective of regular verbs is derived from the imperfective in the way shown in (2) (from Hale, 1965).

(2) gloss	imperfective	perfective
'descend'	'huɖuɲ	'huɖ
'shell corn'	'kɯliw	'kɯl
'split'	'taːpan	'taːp
'ascend'	'tʃiʂaʒ	'tʃiʂ
'vaccinate'	'tʃɯkid	'tʃɯki
'give'	'maːk	'maː

While it is not intended to question the validity of the above analysis, note that the subtractive analysis depends upon there not being any other form from which either of the forms listed in (2) might be derived as well as on the irregular segmental material deleted by the rule, so that it is frequently difficult to be sure of the validity of such an analysis from a few examples. Hale does not comment on speakers' reactions to these forms, but the subtraction illustrated in (2) is part of a wider phenomenon that is treated within a prosodic morphology framework by Hill and Zepeda (1992).

Truncation

Truncation is the removal of some material prior to subsequent affixation. It can be illustrated from the English material in (3).

(3) base (if a word)	*-ate* verb	derivation with *-ate*	derivation with truncation of *-ate*
–	graduate	graduation	graduand
–	inoculate	inoculator	inoculable
–	nominate	nominative	nominee
–	terminate	terminator	terminable
value	valuate	valuator	valuable

Because a whole suffix *-ate* is removed in forming the words in the last column of (3), it appears that this type of truncation is purely morphological. However, its origins may be partly etymological (as with *graduand*) and partly phonological, since it seems that it is the final stress or disyllabic suffix that brings about the shortening. If the subtraction could be shown to be entirely phonological and automatic, it would cease to be considered subtraction and become a form of apocope in sandhi.

In many Muskogean languages, there is truncation before subsequent affixation, but only in certain morphological instances, so that it is less clear that this is truncation rather than an instance of a subtractive morph. Relevant examples are given in (4) (from Broadwell, 1993).

(4) singular verb	plural verb	gloss
balaaka	balka	'lie down'
cokkalika	cokkaka	'enter'
ononkalika	ononkaka	'climb'

Back-Formation

Back-formation is the formation of a new word by the deletion of an affix or supposed affix rather than by the addition of an affix. *Exhibitor* is derived from *exhibit*, but *edit* is derived from *editor* by the deletion of the *-or*.

Clipping

Clipping is the process of removing material from a word while retaining the denotation of the original but leading to a less formal style: *photo* from *photograph* is a case of clipping (or is a clipping). This

process seems to be driven by the prosodic phonology of the material that remains rather than by any morphological principle or by the phonological nature of the material that is deleted.

In a number of well-known cases, the clipping is then embellished (Bauer and Huddleston, 2002) by the addition of a suffix or suffix-like element, so that we get *foot-ball* giving rise to *footy*. Again the phonology of the output seems to drive this process, leading in this particular instance to a preferred word pattern containing a strong–weak foot.

This process may be particularly widespread in hypocoristics, which are also influenced by child-language phonology. *Archie* from *Archibald*, *Betty* from *Elizabeth*, *Peggy* from *Margaret* and other similar forms are morphologically iconic in that the diminution of form reflects the diminution of social distance, but the amount of material deleted and the use or nonuse of the final *-y* is almost certainly determined by the phonological form of the output word.

Blends (*see* **Blend**) seem to be constrained in fundamentally similar ways.

Sudan: Language Situation

A R Mugaddam, University of Khartoum, Khartoum, Sudan

G J Dimmendaal, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

The approximately 29 million inhabitants of Africa's largest country, Sudan, speak at least 135 distinct languages belonging to three different language families, Afroasiatic, Niger–Congo, and Nilo–Saharan (compares Figures 1 and 2). Sudan's current political boundaries were established at the end of the 19th century and the beginning of the 20th century. In 1899, the country was placed under the jurisdiction of Britain as well as Egypt in nominal recognition of the historical claims of the khedive of Egypt, though reserving supreme civil and military authority to an offical nominated by the British colonial government. This so-called 'Condominium Period,' which lasted until the country's independence on January 1, 1956, was preceded by the Turco–Egyptian period, which

process seems to be driven by the prosodic phonology of the material that remains rather than by any morphological principle or by the phonological nature of the material that is deleted.

In a number of well-known cases, the clipping is then embellished (Bauer and Huddleston, 2002) by the addition of a suffix or suffix-like element, so that we get *foot-ball* giving rise to *footy*. Again the phonology of the output seems to drive this process, leading in this particular instance to a preferred word pattern containing a strong–weak foot.

This process may be particularly widespread in hypocoristics, which are also influenced by child-language phonology. *Archie* from *Archibald*, *Betty* from *Elizabeth*, *Peggy* from *Margaret* and other similar forms are morphologically iconic in that the diminution of form reflects the diminution of social distance, but the amount of material deleted and the use or nonuse of the final *-y* is almost certainly determined by the phonological form of the output word.

Blends (*see* **Blend**) seem to be constrained in fundamentally similar ways.

Sudan: Language Situation

A R Mugaddam, University of Khartoum, Khartoum, Sudan

G J Dimmendaal, University of Cologne, Cologne, Germany

© 2006 Elsevier Ltd. All rights reserved.

The approximately 29 million inhabitants of Africa's largest country, Sudan, speak at least 135 distinct languages belonging to three different language families, Afroasiatic, Niger–Congo, and Nilo–Saharan (compares Figures 1 and 2). Sudan's current political boundaries were established at the end of the 19th century and the beginning of the 20th century. In 1899, the country was placed under the jurisdiction of Britain as well as Egypt in nominal recognition of the historical claims of the khedive of Egypt, though reserving supreme civil and military authority to an offical nominated by the British colonial government. This so-called 'Condominium Period,' which lasted until the country's independence on January 1, 1956, was preceded by the Turco–Egyptian period, which

Figure 1 Sudan languages.

Figure 2 Sudan languages – enlarged area.

began in 1821; prior to this era, the Sudan did not form a unified political entity. During Turco–Egyptian rule, Arabic spread as the language of administration in northern and central Sudan. Because of the government's desire for a southward expansion, in order to have access to human resources (slaves) and ivory, male adults from the Blue Nile and the Nuba Mountains were captured and recruited for the army. It was probably in the multilingual garrison camps in the southern Sudan that pidginized versions of Sudanese Arabic emerged that came to be known as 'Nubi' and 'Juba Arabic.' Nubi subsequently became the mother tongue of certain communities that today are also spread over Kenya, Sudan, and Uganda.

The unpopular Turco–Egyptian regime was replaced in 1881 by the Mahdist State, which ruled over two-thirds of Sudan until 1898, when the British, in the scramble for Africa, took over power in Sudan. The British colonial government developed a policy that aimed at the checking of the Arabic language as well as Islam in southern Sudan. In line with a more general policy in their colonies, the colonial government stimulated not only the use of English as an official language, but also the installment of local or regional languages in the educational system. At the Rejaf Conference (1928), for example, six intergroup languages from southern Sudan were selected for development and for use in schools: Bari, Dinka, Ndogo, Nuer, Shilluk, and Zande. Schools in southern Sudan were run mainly by missionaries; nongovernmental schools in the north and missionary schools in the south were only placed under the responsibility of the government in Khartoum in 1957.

Even before independence (1956), the legislative assembly of the country had stated that Arabic should be the official language of the entire country. It also stated that the southern provinces were indivisibly part of Sudan, and this was to be reflected eventually in a new language policy. After independence, northern intellectuals played a significant role in the development and empowerment of Arabic in the south. This policy resulted in the virtual exclusion and neglect of the remaining Sudanese languages. This move was further enhanced by 'Arabizing' secondary and university education in the entire country in the following decades. In the late 1960s, Arabic became the official language of instruction in government schools throughout the country, although at the National Conference for Education in Khartoum it was ordained that southern vernaculars written in Arabic script could be used as media of instruction in the first two years of education in the rural areas of the southern provinces; starting from the third year, however, Arabic should be the medium. From 1972 onward, final examinations in Grade 6 took place in Arabic throughout the country. The issue of language policy and planning in Sudan thus underwent rather dramatic changes in the course of the 20th century.

Arabic probably had spread across Sudan ever since the 8th century, also reaching more remote parts of the (future) country, for example, in the west, between the 16th and 19th century. In areas such as Darfur, Arabic had already developed into an important *lingua franca* before the 19th century. Among several individuals in the region, e.g., ethnic Fur or Daju, this situation resulted in a gradual shift toward Arabic as the primary language of communication, often accompanied by loss of the original first language.

The Sudanese language policy after independence, whereby the crucial instrumental (and integrative) role of Arabic was emphasized and the role of other Sudanese languages (or English) was reduced, had a partly negative effect on attitudes towards local and regional languages. As in other parts of the world, urbanization had an additional catalyzing effect on language attitudes. The studies by Miller and Abu-Manga (1992) and Mugaddam (2002) clearly show that second-generation migrants in the greater Khartoum area, for example, are less likely to acquire the first language of their parents. Although there are differences in language solidarity between the various ethnic groups, there is a clear tendency among second-generation speakers to use Arabic as the first language. In this respect, Khartoum is comparable to many other major urban centers in Africa. In such multilingual areas, there is a strong tendency to switch to the national language of the country (or to an important regional *lingua franca*) for daily communication purposes.

Whereas today Sudanese Arabic is used widely in the streets, in the markets, and in government and educational institutions across the country, vernaculars are used mainly within their immediate speech communities, although there are differences in language attitudes between the different generations as well as between ethnic groups (Mugaddam, 2002). For example, Sudanese from Darfur, the Nuba Mountains, or northern regions use more Arabic in their everyday communication than do ethnic groups from the south.

Southern resistance against the predominant role of Arabic and the Islamicization of the entire country resulted in a civil war in Sudan between 1955 and 1972 as well as between 1983 and 2004. In the Addis Ababa Peace Agreement (1972), Arabic was recognized as the official language, and English was recognized as the principal language for the southern region (without prohibiting the official use

of languages that may serve as practical nesessities for the executive and administrative functions of the regions). In the same year, the 'Language Survey of Sudan' was initiated by the Institute of African and Asian Studies at the University of Khartoum (after similar surveys had been conducted in Ethiopia, Kenya, Tanzania, and Uganda) in order to investigate patterns of language use with an eye on future language policies. The Addis Ababa Peace Agreement did not fully realize its objectives because of the renewed outbreak of civil war in the south in 1983. Interestingly, although subsequent Sudanese governments did not support the official use of languages other than Arabic, nongovernmental organizations in Sudan developed orthographies and produced primers over the past recent decades for more than 60 different languages.

In 2004, a peace protocol was signed by the government of Sudan and the Sudan People's Liberation Movement. This so-called 'Naivasha Peace Protocol' also contains important statements concerning the linguistic situation in Sudan: (1) All the indigenous languages are national languages that shall be respected, developed, and promoted; (2) The Arabic language is the most widely spoken national language in Sudan; (3) Arabic, as a major language at the national level, and English shall be the official working languages for national government business and for instruction in higher education; (4) In addition to Arabic and English, the legislature of any subnational level of government may adopt any national language(s) as additional official working language(s) at its level; and (5) The use of either language at any level of government or education shall not be discriminated against.

Patterns of language use in modern Sudan suggest that many local languages are facing imminent death if nothing is done to implement this new language policy and to sustain linguistic and cultural diversity in the country.

Languages

Figures with respect to the number of speakers for some languages in Sudan date back to the early 1950s, while for others, the most recent census goes back to the early 1990s. Moreover, languages assumed to be extinct such as Birgid (Birked), still appear, in fact, to have speakers. Consequently, some of the figures below are unreliable, and this fact should be borne in mind with regard to them.

Acheron (?)
Acholi (27 000)
Afitti (4512)
Aja (200)
Aka (200)
Ama (70 000)
Anywak (52 000)
Arabic (Sudanese Arabic: at least 15 million; Nubi? Juba Arabic?)
Atuot (50 000)
Avokaya (15 000)
Baale (5000)
Bai (2500)
Baka (25 000)
Banda-Banda (?)
Banda-Mbrès (?)
Banda-Ndélé (?)
Banda, Mid-Southern (?)

Sumerian

G Cunningham, University of Oxford, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Sumerian – a long-dead language isolate documented throughout the Middle East, in particular in the south of what is now Iraq – rivals ancient Egyptian as the earliest written language. The first sources date to the late 4th millennium B.C.E. and the last to the 1st century C.E. When the language ceased to be spoken is uncertain: some estimates date this to the early 2nd millennium B.C.E. It was subsequently an elite language, used only in royal, ritual, and scholarly contexts. The language's users referred to it as *eme gir*, possibly meaning 'native tongue', the term *Sumerian* being an anglicization of Akkadian *Šumeru*. The grammar outlined here is based on documents from the far south in the late 3rd millennium B.C.E., benefiting from unpublished work by Bram Jagersma, but it applies broadly to other places and periods.

Phonology

Fifteen consonants are used in transliterating Sumerian: <b, d, g, g̃ (/ŋ/ as in ***sing***), ḫ (/x/ as in *lo**ch***), k, l, m, n, p, r, s, š (/ʃ/ as in ***sh**ip*), t, z>. The language also had at least two weak consonants <y, ʾ (/ʔ/ glottal stop)>, which were subject to phonological change or loss in certain environments, and eight vowel phonemes, short and long <a, e, i, u>. Neither vowel length nor weak consonants are indicated in transliteration. These alphabetic representations should be regarded as approximations. Vowel assimilation, both anticipatory and perseverative, is extensive, resulting in considerable allomorphic variation.

Word Classes

Nouns and verbs are the primary open word classes. In addition to numerals, the language has small closed classes of adjectives, adverbs, conjunctions, circumpositions, and interjections, as well as related sets of pronouns (personal, demonstrative, indefinite, interrogative, and reflexive) and determiners (possessive, demonstrative, and an indefinite). Most determiners cliticize to whatever class of word precedes them, as do plural marking and case marking. In the cuneiform script used to record Sumerian, lexical words are typically written logographically and all function morphemes (bases, clitics, and affixes) phonographically. Signs that constitute a word are linked by hyphens in transliteration, as are enclitics to their host. Given our uncertainty about the phonological form of many words, transliteration is simply a sign-by-sign representation of what was written.

Morphology

In terms of morpheme segmentation, Sumerian is more agglutinating than fusional. Inflectional affixation is restricted to verbs. Like verbs, nouns and adjectives can have reduplicated bases. Possibly, in nouns this expresses universality, in dynamic verbs iterativity, and in stative verbs intensity; its function in adjectives is unclear.

New nouns are mainly formed by compounding; new verbs are formed as by multiword expressions in which a noun and verb combine as a semantic unit, resulting in many three-place transitive predicates, such as:

ǧiš tag
wood touch
'touch wood to something (i.e., sacrifice something)'

Nouns and Phrases

Nouns are marked for gender, although this distinction appears morphologically in only the pronominal morphemes and syntactically only in restrictions that relate to plural and case marking. The gender distinction is between human (people and deities) and nonhuman (animals and inanimates), with some socially conditioned exceptions; in addition, nonhuman pronominal morphemes can refer to groups of people or deities. Only human nouns are marked for number.

At the level of the noun phrase, the language is left-headed, the sequence in outline being:

noun, modifier(s), determiner, plural marker, case marker

although the indefinite and most demonstrative determiners do not occur with modifiers.

Case markers typically indicate the syntactic role of the phrase in the clause. The core functions of the subject and direct object are marked by the ergative (*e* = transitive subject) and absolutive (Ø = intransitive subject and transitive direct object). Zero-marking is also used for personal pronouns as subject of both intransitive and transitive verbs. Noun phrases with a noun as head consequently follow ergative-absolutive alignment, whereas those with a personal pronoun as head follow nominative-accusative alignment. Personal pronouns occur infrequently (expressing emphasis or contrast); the language has person-number-gender (PNG) affixes in the finite verbal forms that index these core functions.

Table 1 Sumerian noncore case morphemes

Phrase-final enclitic		*Translation guide*	*Equivalent verbal prefix*	
Local				
Dative (human only)	*r(a)*	'to/for'	Dative	*a*
Directive (nonhuman only)[a]	*e*			
Dative (human only)	*r(a)*	'in(to) contact with'	Directive[a]	*i*
Directive (nonhuman only)[a]	*e*			
Dative (human only)	*r(a)*	'on(to)'	Directive[a]	*i* and
Locative (nonhuman only)	*ʾa*			*y* (>*e*)
Locative (nonhuman only)	*ʾa*	'in(to)'	Locative (nonhuman only)	*n(i)*
Terminative	*š(e)*	'to(ward)'	Terminative	*ši*
Ablative	*ta*	'from'	Ablative	*ta*
Comitative	*d(a)*	'(together) with'	Comitative	*da*
Manner				
Equative	*gin*	'like'	None	
Adverbiative	*eš*	'in the manner of'	None	

[a]The directive is sometimes referred to as the locative-terminative.

Table 2 Sumerian finite verb[a]

Extra-inflectional prefixes	*Noncore prefixes*	*Core affixes and verbal base*
a(*l*) or *i*	Noncore PNG	Core PNG
Clause connective: *nga*	Dative	Verbal base
Cislocative: *m*(*u*)	Comitative	Aspect: *e*(*d*) or Ø
Middle passive: *ba*	Ablative or terminative	Core PNG
	Directive or locative	

[a]PNG = person-number-gender marker.

Table 1 shows the noncore adverbial case markers, arranged to reflect their relationship with a more nuanced set of morphemes incorporated in finite verbal forms. Like case markers, the verbal prefixes are postpositional in that they can be preceded by a noncore PNG prefix (see Table 2).

A further case marker, the genitive, is typically adnominal, marking noun phrase to noun phrase relations. It encompasses a much wider semantic field than possession. Genitive noun phrases may occur in the modifier(s) slot:

bad$_3$	iri	kug-ga-ka-ni
bad	iri	kug = ak = ani = Ø
wall	city	holy = GEN = POSS.3.SING = ABS

'her wall in the Holy City'

(In this example, the first line is a transliteration of the script, in which the subscript numeral in *bad*$_3$ is a modern convention that distinguishes between homophonous signs; the second line is a morphemic representation, in which = marks a clitic boundary.) This example indicates two characteristics of the script: (1) There is not always a one-to-one correspondence between morpheme and sign and (2) the reduplicated writings of consonants often appear to have no phonological implications.

When genitive noun phrases express only possession, they have two characteristics: They are in complementary distribution with possessive determiners, and they can be shifted to the beginning of the clause, in which case a possessive determiner then is added to the original phrase (NHUM stands for nonhuman):

e$_2$-a	ni$_2$	
e = ak	ni	
temple = GEN	awesomeness	
gal-bi	gal = bi = Ø	great = POSS.3.NHUM = ABS

'the temple's great awesomeness'

Here the genitive is written *a*, the form used when it is not followed by a vowel.

Verbs and Clauses

Given that the dependents of a verb can be expressed in pronominal form by verbal affixes, a clause can consist only of a finite verb. However, in a clause that includes noun phrases, the language is right-headed, the typical order being subject(–object)–verb.

A few verbs are irregular, having a different base depending on aspect and/or number; they can be divided into two major classes: reduplicating and suppletive. Plural bases are restricted to suppletive verbs; they are mostly used with a plural intransitive subject or direct object and thus follow ergative-absolutive alignment.

The Sumerian aspect and/or tense categories are difficult to reconstruct. Many Sumerologists have adopted instead two terms used by Akkadian grammarians, *ḫamṭu* ('quick') and *marû* ('fat'). However, the principal distinction in finite verbal forms may be

Table 3 Sumerian core (subject and direct object) affixes in finite verb

	Intransitive	*Transitive*			
	Both aspects	*Completive aspect*		*Incompletive aspect*	
	Subject suffix	*Subject prefix or circumfix*	*Direct object suffix*	*Direct object prefix*	*Subject suffix*
1 HUM SING	*en*	*ʾ*	*en*	*ʾ*	*en*
2 HUM SING	*en*	*y*(>*e*)	*en*	*y*(>*e*)	*en*
3 HUM SING	Ø	*n*	Ø	*n*	*e*
3 NHUM	Ø	*b*	Ø	*b* or Ø	*e*
1 HUM PL	*enden*	*ʾ . . . enden*	*enden*	*me*	*enden*
2 HUM PL	*enzen*	*y*(>*e*) . . . *enzen*	*enzen*	—	*enzen*
3 HUM PL	*eš*	*n. . .eš*	*eš*	*nne*	*ene*

between completive and incompletive aspects (*ḫamṭu* and *marû,* respectively). Nonfinite forms are more nuanced and have stronger temporal connotations, distinguishing between completive (typically with past reference), habitual (typically with present reference), and incompletive (typically with nonpast reference).

Stative verbs are excluded from incompletive aspect and only context indicates whether they have past or nonpast reference. In nonfinite verbal forms, intransitive stative verbs are in completive aspect and transitive ones are in habitual aspect. The copular verb is also excluded from incompletive aspect. It conjugates like an intransitive verb and is attested in both enclitic (prefixless) and independent forms.

Nonfinite verbal forms function as verbal adjectives and nouns, and in nonfinite relative and adverbial clauses (for example, of purpose and time). Their inflection comprises a prefix expressing negation, base reduplication, and an aspect suffix (*ʾa* = completive; Ø = habitual; *ed(a)* = incompletive). In addition, irregular verbs have a different base in incompletive aspect.

As Table 2 indicates, the morphology of finite verbal forms can be much more complex, although a form may be as simple as a prefix, a base, and a subject affix. In addition to the base changing of irregular verbs, finite intransitive forms are marked for aspect with a suffix and transitive forms are marked with the morphology of the core PNG affixes. Setting aside plural PNG affixes, some of which are poorly attested whereas others are circumfixes, Table 3 shows that alignment in completive aspect follows ergative-absolutive principles; in incompletive aspect, it is nominative-accusative in the first and second persons but tripartite in the third person.

Partly on morphological grounds and partly because they have clausal scope, further bound morphemes can be regarded as clitics. These include an enclitic relativizer-complementizer *ʾa* and a set of proclitics that either connect clauses, such as *u* 'after', or change mood or polarity (CISL stands for cislocative):

ḫu-mu-na-ab-šum$_2$-mu
ḫu=mu-nn-a-b-šum-u
M=CISL-3.SING-DAT-DO.3.NHUM-give-SUBJ.3.SING
'he must give it to him'

This example illustrates a further characteristic of the script: There is not always a one-to-one correspondence between sound **syllable** and sign, [nab] being written <na-ab> and [mun] being written simply as <mu>. The transitive subject prefix is an instance of perseverative assimilation from *e* to *u*.

Neither the cohortative (first person) nor the imperative (second person) distinguishes aspect, having instead hybrid forms that combine completive bases with incompletive direct object affixes. Both delete the singular intransitive and transitive subject and can therefore be regarded as following nominative-accusative alignment. The imperative is further irregular in that it is formed not with prefixes but with suffixes.

Resources

The most comprehensive grammar of Sumerian is Attinger (1993: 141–314), although in places it requires familiarity with an earlier, subsequently expanded, publication, Thomsen (2001). No full print dictionary has been published; a web-based dictionary is under development.

See also: Akkadian; Mesopotamian Cuneiform Script.

Summarization of Text, Automatic

I Mani, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The goal of automatic text summarization is to take a source document as input, extract information content from it, and present the most important content to the user in a condensed form in a manner sensitive to the user's or application's needs. This goal has been pursued in research and development activities since the 1950s. With the rapid growth of on-line information and services in the 1990s, research and development in this field has grown considerably in scope and importance. In addition to the practical interest, summarization is of interest as an application that potentially involves many different aspects of natural language processing, including both analysis and generation of text.

Summarization by humans is familiar to us in everyday life, from abstracts of scientific papers, newspaper headlines, highlights of meetings, bulletins such as weather forecasts and stock market updates, abridged books, biographies, video clips, maps, etc. Summarization by machines is somewhat less familiar, but there are a number of research systems in use today that produce summaries of various kinds. In addition to summarizers of Web search engine results, there are systems that can produce summaries of multimedia news broadcasts, aids to physicians that summarize and compare the recommended treatments for a patient in the medical literature, systems that can summarize meetings based on audio recordings, summarizers that build biographical dossiers of people from information on the web, a tool that builds book summaries for hand-held displays, a summarizer that shortens text and then synthesizes it as speech to help the blind, etc. Columbia University's Newsblaster system shown in **Figure 1**, has, for the last several years, automatically produced news summaries by fusing information from multiple news reports on the web.

Terminology

Let us first begin with some basic terminology. One dimension of summarization has to do with the extent to which the summary contains information from the source. An **extract** is a summary consisting entirely of material copied from the input. An **abstract** is a summary at least some of whose material is not present in the input, e.g., subject categories, paraphrase of content, etc. Abstracts that include new sentences that were not in the source rely on some form of natural language generation.

Another dimension has to do with what sort of purpose the summary serves. An **indicative abstract** provides a reference function for selecting documents for more in-depth reading. Thus, a summary that only provided a short headline for a radio broadcast would be indicative. An **informative abstract** covers all the salient information in the source at some level of detail. The indicative/informative distinction is a prescriptive distinction, intended to guide professional abstractors. Thus, professional abstractors are instructed to use indicative abstracts for less-structured documents such as editorials, essays, opinions, or for lengthy documents, such as books, conference proceedings, annual reports, etc., whereas informative abstracts are generally used for other documents. In the case of reports of scientific investigations, indicative abstracts should contain information about an article's purpose, scope, and approach, but not results, conclusions, and recommendations; informative abstracts, on the other hand cover all these different aspects. Finally, a **critical abstract** evaluates the subject matter of the source, expressing the abstractor's views on the quality of the work of the author, as in the case of a movie preview or book review. Given the difficulty of getting a computer to understand natural language text, having it offer an opinion on a source is not considered an appropriate task for a machine, and thus critical summaries by machines are not on the horizon.

Yet another terminological distinction has to do with the audience of a summary. **Generic** summaries are

Summarization of Text, Automatic

I Mani, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The goal of automatic text summarization is to take a source document as input, extract information content from it, and present the most important content to the user in a condensed form in a manner sensitive to the user's or application's needs. This goal has been pursued in research and development activities since the 1950s. With the rapid growth of on-line information and services in the 1990s, research and development in this field has grown considerably in scope and importance. In addition to the practical interest, summarization is of interest as an application that potentially involves many different aspects of natural language processing, including both analysis and generation of text.

Summarization by humans is familiar to us in everyday life, from abstracts of scientific papers, newspaper headlines, highlights of meetings, bulletins such as weather forecasts and stock market updates, abridged books, biographies, video clips, maps, etc. Summarization by machines is somewhat less familiar, but there are a number of research systems in use today that produce summaries of various kinds. In addition to summarizers of Web search engine results, there are systems that can produce summaries of multimedia news broadcasts, aids to physicians that summarize and compare the recommended treatments for a patient in the medical literature, systems that can summarize meetings based on audio recordings, summarizers that build biographical dossiers of people from information on the web, a tool that builds book summaries for hand-held displays, a summarizer that shortens text and then synthesizes it as speech to help the blind, etc. Columbia University's Newsblaster system shown in Figure 1, has, for the last several years, automatically produced news summaries by fusing information from multiple news reports on the web.

Terminology

Let us first begin with some basic terminology. One dimension of summarization has to do with the extent to which the summary contains information from the source. An **extract** is a summary consisting entirely of material copied from the input. An **abstract** is a summary at least some of whose material is not present in the input, e.g., subject categories, paraphrase of content, etc. Abstracts that include new sentences that were not in the source rely on some form of natural language generation.

Another dimension has to do with what sort of purpose the summary serves. An **indicative abstract** provides a reference function for selecting documents for more in-depth reading. Thus, a summary that only provided a short headline for a radio broadcast would be indicative. An **informative abstract** covers all the salient information in the source at some level of detail. The indicative/informative distinction is a prescriptive distinction, intended to guide professional abstractors. Thus, professional abstractors are instructed to use indicative abstracts for less-structured documents such as editorials, essays, opinions, or for lengthy documents, such as books, conference proceedings, annual reports, etc., whereas informative abstracts are generally used for other documents. In the case of reports of scientific investigations, indicative abstracts should contain information about an article's purpose, scope, and approach, but not results, conclusions, and recommendations; informative abstracts, on the other hand cover all these different aspects. Finally, a **critical abstract** evaluates the subject matter of the source, expressing the abstractor's views on the quality of the work of the author, as in the case of a movie preview or book review. Given the difficulty of getting a computer to understand natural language text, having it offer an opinion on a source is not considered an appropriate task for a machine, and thus critical summaries by machines are not on the horizon.

Yet another terminological distinction has to do with the audience of a summary. **Generic** summaries are

Figure 1 Columbia University's Newsblaster.

aimed at a broad readership community. **Topic-focused** summaries (also known as tailored, user-focused, or query-focused summaries) are tailored to the requirements of a particular user or group of users. Summaries tailored to the user's interests can be based on full-blown models of the user's interest, profiles recording subject area terms, or a specific user query (as in summaries tailored to search engine users).

The main business of a summarizer is, of course, the condensation of information. The compression rate (or reduction rate), is usually measured in terms of length, e.g., a fixed number of sentences or words, or the summary length divided by the source length. In carrying out this condensation, a summary needs to satisfy two informativeness criteria: (i) the summary needs to be faithful to the source, in terms of representing its information content, and (ii) the summary needs to be relevant to the needs of the user and task. The need to represent information content of a source leads to a notion of salience of information in the source. Even in the case of a generic summary, there is some implicit audience for the summary; in the case of a topic-focused summary, the particular user's interests need to be taken into account. A topic-focused summarizer needs to take into account the influence of the user as well as content of the document, and can include a parameter to control the relative weights of these two factors.

In addition to informativeness, a summary needs to be coherent. In the case of an extract, when the extracted sentences are far apart in the text, the gaps between them can result in incoherence. Anaphors present in an extracted sentence will need to have their referents present in the summary, otherwise they will dangle. Particular structures in the source, such as tables, lists, etc., need to be recognized, otherwise incoherence will result. Finally, in the case of abstracts that rely on natural language generation, there is a need to ensure that the new text generated is coherent, as well as grammatical. In some applications, however, where fragmentary output is acceptable, such as summaries on cell-phones where short phrases may be desired, coherence may be less of an issue.

Human Abstractors

Among the communities of people who write summaries for a living are professional abstractors working

for abstracting services and information publishers. In addition, researchers, journalists, editors, and news analysts at various newspapers and industry newsletters, editors at scientific journals, etc., may carry out summarization as part of their jobs. The few insights we have about how abstractors carry out their tasks comes from several sources: (i) codification of abstractors' best practices in terms of prescriptive guidelines, (ii) studies of abstractors working in a laboratory setting, (iii) analysis of the structure of abstracts of scientific articles, and (iv) mapping of certain sets of abstracts to their source texts. I now briefly discuss these sources of information.

Guidelines

Expert knowledge on how to write effective abstracts has been codified into guidelines by Cremmins (1996). Since abstractors work at high speeds, they avoid trying to build a deep understanding of the text (as a student might), instead searching for key content that can be used in the abstract. In a scientific article, the abstractor will initially focus on sections identifying key components such as the purpose, scope, methods, results, and conclusions. This information is then transformed and then synthesized into a draft abstract. The draft abstract is eventually revised to ensure that the maximum amount of relevant information has in fact been packed into the available compression. These revisions involve editing operations such as dropping redundant and vague terms, substituting terms with other prescribed ones, adjusting references, using standard terminology, making context-dependent lexical adjustments, and a variety of cut-and-paste operations.

Abstracting Behavior

Studies of professional abstractors in a laboratory setting (Endres-Niggemeyer, 1998), where the abstractors were asked to think aloud as they worked, indicate that they do not read the document from start to finish. Instead, abstractors use the structural organization of the document to skim the document for relevant passages, which are fitted together into a discourse-level representation of the key components. The skimming for relevant passages exploits specific shallow features such as cue phrases (especially in-text summaries), location of information in particular structural positions (beginning of the document, beginning and end of paragraphs), and information from the title and headings. In the synthesis phase, abstractors tend to cut and paste from the source text. While they do use generalization operations that provide information that characterizes source information in more general terms, they stay close to the text rather than summarize it in their own words.

Analysis of Empirical Abstracts

Several studies of existing bodies of abstracts produced by professional abstractors reveal key components common to them. For example, Liddy (1991) elicited information from professional abstractors as to the key components they thought were found in abstracts, and then tested which of these components were actually present in a corpus of 276 abstracts of articles reporting empirical research. She found that abstracts in the corpus were characterized by the following key components: purpose, hypotheses, methodology, subjects, results, conclusion, and references. Such key components reflect the interaction of prescriptive guidelines with genre-specific discourse-level organizing principles that allow for effective summarization.

Relation of Abstracts to Sources

Since humans construct abstracts by interpreting source documents, the relationship between the two is a key issue relevant to automatic summarization. Studies that compare summary sentences with source sentences for similarity of content reveal that a majority of summary sentences are indeed very similar to source sentences, suggesting that they are cut and pasted from the source.

In making such comparisons, similarity can be automatically assessed by a program that does pair-wise comparisons of summary sentences and source sentences based on content word overlap, i.e., after throwing out function words such as determiners, prepositions, pronouns, and other words on a stop-list. Such an analysis of sentences in terms of its content words (and/or phrases) represented in some form and possibly their frequencies is called a **bag-of-terms** representation. (In such representations, terms are often normalized by stemming, i.e., by shaving off inflectional affixes.)

The extent to which cutting and pasting occurs, and the exact form of it, depends on a number of factors, including the type of instructions and training given to the abstractors, and the extent to which they are instructed to use their own words. Kupiec *et al.* (1995) discovered that 79% of summary sentences in a corpus of 188 summaries written by professional abstractors had similar content to a source document sentence. Studies have also exposed the type of cut-and-paste operations involved; for example, Jing and McKeown (1999) found from a small study of 15 human-written summaries that 78% of summary sentences could be traced to specific cut-and-paste operations from the source document, including sentence truncation and sentence aggregation, lexical paraphrasing, generalizations and

Figure 2 Abstract architecture for summarization; from Mani (2001) with permission.

specializations of information in the source, and sentence reordering.

Challenges

The insights derived from the above sources have helped guide some of the research in automatic summarization. However, many more studies are needed, both of professional abstracting techniques as well as analysis of corpora consisting of abstracts produced by professional abstractors along with their source documents. There are many open questions. For example, how do the strategies vary with different compression rates? What is the minimum level of understanding of the subject matter needed to produce an abstract? How much do professional abstractors working within a given organization and following the same set of guidelines differ in their abstracts? Such studies can only help improve summarization systems.

Summarization Approaches: Overview

Overall, one can conceive of a summarizer as comprising three possibly interleaved phases: (i) analysis of the source text to produce an internal representation, (ii) transformation of the internal representation into a condensed summary representation, and (iii) synthesis of the resulting summary from the internal representation. The summarizer carries out a variety of condensation operations, primarily **selection** of elements, **aggregation** (or merging) of elements, and **generalization** (substitution of elements with more general ones). An abstract architecture for summarization is shown in Figure 2.

There are two broad classes of summarization approaches. The shallow approaches aim at sentence extraction, and use relatively simple methods that do not require extensive amounts of linguistic knowledge. The synthesis phase in such approaches is primarily aimed at smoothing the text to address gaps and dangling references, by including a window of previous sentences or by adjusting references (discussed below). Linguistic knowledge used in analysis does not have to be extended for each domain. Deeper approaches aim at producing abstracts. Here synthesis involves natural language generation, which requires some coding of knowledge for each new domain.

Producing Extracts

Early Approaches

The earliest approaches to automatic summarization grew out of Luhn's work (1958) Luhn laid the foundations for a statistical approach to summarization based on examining the frequency of content words in the document. Low-frequency terms were removed, and sentences were weighted based on the density in the sentence of the resulting set of significant terms. This was based on dividing each sentence into segments bracketed by significant terms not more than four nonsignificant terms apart. Each segment was scored by taking the square of the number of bracketed significant terms divided by the total number of

bracketed terms, and the score of the highest scoring segment was taken as the sentence score. The highest weighted sentences were then included in the summary.

Edmundson (1969) extended Luhn's work to look at other features in addition to term frequency: cue words that were suggestive of information salience (e.g., *significant*, *impossible*, *hardly*), document title and heading words, and the position of sentences in the document (sentences under headings, near the beginning or end of a paragraph or the document). He conducted a number of experiments using linear combinations of features, where each feature was given a particular weight. He found that the three additional features outperformed word frequency measures in comparison against manual summaries, with position in the document being the best individual feature and term frequency the worst; a combination of cue words, title, and position features outperforming other combinations and the individual features.

Modern Approaches

Subsequent work has used a richer model of term frequency, counting morphological variants as tokens of the same term, and normalizing for the length of the document as well as the overall frequency of the term in a corpus of documents. Later work has also reinforced Edmundson's observation that term frequency is less informative than features such as position, cue words, or title information. Cue words (and phrases), including in-text summaries (e.g., *in summary, the purpose of this article is, in conclusion*) tend to be genre-specific; scientific articles will use different cue phrases to signal salient information compared to, say, TV news. Most systems use genre-specific rules for extracting cue phrases.

Discourse-Level Features Additional features that have been investigated include discourse-level features. I discuss two classes of features here: those based on text cohesion and those based on text coherence.

Text cohesion (Halliday and Hasan, 1976) has attracted a great deal of interest in automatic summarization. Text cohesion involves relations between words, word senses, or referring expressions, which determine how tightly connected the text is, and it is expressed in terms of links in text, called ties, which express semantic relationships. Text cohesion includes grammatical cohesion, involving linguistic relations such as anaphora, ellipsis, and conjunction; and lexical cohesion, which involves relations such as reiteration, synonymy, and hypernymy (e.g., *dog* is-a-kind-of *animal*). There is evidence (Irwin, 1980) that having more cohesive ties influences the summarizability of texts.

Figure 3 A graph representing cohesion links between paragraphs (Salton *et al.*, 1997).

A natural way of representing text cohesion for computational purposes is capturing it in the form of a graph structure. Here the nodes are text elements, and the edges are links between text elements. Typically, the text element chosen is a word, though smaller elements like word-stems or larger elements like phrases and sentences or paragraphs may be chosen instead. The relations involved are the cohesion relations described above. The basic idea of representing texts in terms of graphs is that the topology of the graph will reveal something interesting about the salience of information in the text. In particular, nodes that are connected to lots of other nodes are likely to carry salient information. Graphs where the nodes are paragraphs and the relations are those of similarity of content between paragraphs (computed in terms of a measure of bag-of-terms vocabulary overlap) have been used for summarization by Salton *et al.* (1997). Here paragraphs that are connected to many other paragraphs (i.e., bushy nodes in the graph) with a similarity above a particular threshold (set by trial and error) are considered salient, since they would very likely contain topics discussed in many other paragraphs. A graph generated by such methods is shown in Figure 3.

The representation of cohesion relations is closely related to the problem of segmenting a text into topics. A topic may be thought of as a text segment that is about one main concept. In Figure 3, two topics are shown emerging from the graph. Segmentation methods that break up text into topical regions based on similarity between successive blocks of text (Hearst, 1997) have been used in summarization in a variety of approaches.

I now turn to **text coherence**. There have been a large number of theories of text coherence, based on representing the overall structure of a multi-sentence

Figure 4 A RST tree for a text; from Marcu (1999).

text in terms of macro-level relations between clauses or sentences. A sample text annotated using coherence relations based on rhetorical structure theory (RST) (Mann and Thompson, 1988) is shown in Figure 4. The subject here is the weather on Mars.

RST assumes that most rhetorical relations reflect asymmetric relationships between a nucleus unit (which is more central to the writer's goals) and a satellite unit (which is ancillary to the writer's goals, indicated with dotted boxes in Figure 4). Assuming that nuclei are more salient than satellites, salience of information in the text can be determined by having each parent node identify its nuclear children as salient, promoting them to the parent's level. The salience of an elementary discourse unit (a terminal node) is determined by how high in the tree it gets promoted. Based on this simple promotion method, we have the following ranking of clauses in order of decreasing discourse salience: $2 > 8 > \{3, 10\} > \{1, 4, 5, 7, 9\} > 6$; here clauses in parentheses are equally ranked. This means that if we want a four-sentence summary, the one below will be produced:

Mars experiences frigid weather conditions.
Most Martian weather involves blowing dust or carbon dioxide.
Surface temperatures typically average about −60 degrees Celsius (−76 degrees Fahrenheit) at the equator and can dip to −123 degrees C near the poles.
Yet even on the summer pole, where the sun remains in the sky all day long, temperatures never warm enough to melt frozen water.

The key finding here (Marcu, 1999) on a small collection of five texts is that there is a strong positive correlation between the nuclei of the RST tree for a text and what subjects believe are the most important units of text. While this falls short of a full comparison against summaries, the results are nevertheless encouraging.

A program to automatically construct RST trees developed by Marcu first hypothesizes possible rhetorical relations between elementary discourse units based on the presence of discourse markers, and then uses a search procedure to find all discourse trees compatible with the constraints, using this information to score each tree, returning the tree with maximal weight. The program has been evaluated only on the collection of five texts, where it was found that the program's trees did not correlate well with those of the analysts.

The challenge in defining RST trees is deciding on the rhetorical relations; discourse markers may be absent (as in the second and third sentences of Figure 4), and the precise relation may not be clear. An annotation experiment by Marcu and his colleagues found high inter-judge agreement in human annotation of a corpus of 90 texts; however, this involved expert annotators who were allowed to revise the annotation instructions based on joint discussion and agreement.

Discourse-based information is overall of great interest to summarization. The challenges faced by research include getting a better handle on discourse processing, in terms of consistent definitions of discourse structure and accurate and efficient implementation of it.

Framework for Sentence Extraction We can summarize our discussion of shallow methods in the following framework. The analysis phase of summarization involves feature extraction. The transformation phase involves feature combination, with weighting of different features. The synthesis phase involves sentence selection to produce a rough draft, and revision of this draft to improve coherence of the output summary. The problem of extracting sentences is thus viewed as one of sentence weighting, based on finding an appropriate set of sentential features and a feature combination method. We can characterize the sentence weighting, as a first approximation, in terms of a weighted sum of the values of abstract features found in the sentence, expressed by Equation (1):

$$\begin{aligned} Weight(S) := {} & \alpha \times Location(S) + \beta \times CuePhrase(S) \\ & + \chi \times ThematicTerm(S) \\ & + \delta \times DiscourseSalience(S) \\ & + \gamma \times RelevantTerm(S) \end{aligned} \tag{1}$$

Here S is a sentence. *Location* is the weight assigned to a sentence based on its position, e.g., whether it occurs in initial, medial, or final position in a paragraph or the entire document, or whether it occurs in prominent sections such as the document's introduction or conclusion. *CuePhrase* is the weight assigned to the sentence based on the presence of cue phrases in it. *ThematicTerm* is the weight assigned to a sentence based on the presence of high-frequency terms, where the frequencies are normalized in some way. *DiscourseSalience* is the weight assigned to the sentence based on its salience in terms of topics, cohesion relations, or rhetorical structure. *RelevantTerm* is the weight assigned to a sentence in terms of presence in it of information that is also in the title, headline, initial paragraph, or the user's profile or query. The Greek letters denote tuning parameters that identify the relative importance of each of the features. This set of abstract features is hardly exhaustive; they could be expanded to include sentence length, presence of proper names or citations, etc.; the key, in the shallow approach, is discovering good features.

Corpus-Based Approaches The attractiveness of Equation (1) lies in its simplicity. Many sentence extraction techniques in use today are based on this model. However, determining what features to consider, as well as what particular weight a feature should have, is a real issue. The latter determination is likely to be very genre-dependent; for example, material at the end of the text may be important in scientific articles (e.g., in the conclusion), whereas the first few sentences may be important in a news story. In TV news, a preceding segment before a commercial may provide summary information in terms of a preview of the next story to come. Approaches that are trainable based on a corpus of texts in the genre for which summaries are desired, are therefore of considerable interest.

In such approaches, the corpus consists of source documents and their summaries. The system extracts features from each sentence of each source document, constructing an array of feature values, called a feature vector. For example, the vector [1.0 0 0.6 0 0.3] may represent a sentence with value 1.0 for *Location* (e.g., it might be in the introduction), value 0 for *CuePhrase* (it contains no cue phrases), value 0.6 for *ThematicTerm* (e.g., it contains three highly frequent terms out of its five content words), value 0 for *DiscourseSalience*, and value 0.3 for *RelevantTerm*.

Each feature vector is labeled as summary-worthy or not based on whether the source document sentence is considered a summary sentence or not. These labeled feature vectors are fed to a machine-learning program, which tries to learn, from the positive and negative examples provided, rules or functions that will discriminate summary-worthy feature vectors from others. A held-out set of documents is then tested against the rules, with the sentences in the test documents converted to feature vectors, with the rules identifying those sentences that are summary-worthy.

There are a number of issues that have to be addressed in taking a corpus-based approach. The choice of corpus is critical. Its size, the availability of summaries (either extracts or abstracts), and the quality of the summaries (in terms of compression rate, adherence to abstracting guidelines, and overall coherence of the abstract) are obviously important. Discovering the right set of features for a particular problem is an art, and is usually based on prior

research and trial and error, though a machine can certainly help in this process.

Since the learning requires training data where a source document sentence is labeled as summary-worthy based on comparison with the summary, the labeling method is also important. If the summary is an extract (i.e., a set of extracted sentences), then a source sentence can be labeled as summary-worthy if it is found in the extract. If the summary is an abstract, there are a number of choices of labeling methods. The abstract can be mapped back to the source text via an alignment program, yielding an extract. Otherwise, each source document sentence can be compared for similarity of content with the abstract as a whole, or with each sentence of the abstract, based on some bag-of-terms vocabulary overlap measure.

The choice of learning algorithm is not as challenging a problem, as there are many such algorithms available freely, allowing for easy comparison of different algorithms. Consider, for example, a Bayesian sentence classifier from the abovementioned work of Kupiec *et al.* (1995). The classifier needs to compute the probability of a sentence s being included in extract E, given the sentence's feature-value pairs, i.e., $P(s \in E|F_1, \ldots, F_n)$. Using Bayes's Rule, this is equal to the probability of seeing the features given that the sentence is in the extract, multiplied by the prior probability $P(s \in E)$ of a sentence belonging to the extract (i.e., the compression rate), divided by the prior probability of seeing the features. This idea is formally expressed in Equation (2a), which can be approximated as Equation (2b).

$$P(s \in E|F_1,\ldots,F_n) = \frac{P(F_1,\ldots,F_n|s \in E)P(s \in E)}{P(F_1,\ldots,F_n)} \quad (2a)$$

$$P(s \in E|F_1,\ldots,F_n) \approx \frac{\prod_{j=1}^{n} P(F_j|s \in E)P(s \in E)}{\prod_{j=1}^{n} P(F_j)} \quad (2b)$$

To simplify matters, the features can be discretized as Boolean-valued (1 or 0).

To train a sentence classifier for topic-focused summaries, the *RelevantTerm* feature in Equation 1 has to be specified. Clearly, the learner has to learn how to summarize a document with respect to any topic (or query), not just summaries specific to topics found in training. One way to address this is to use specific topics during training, but to allow for *RelevantTerm* features that could potentially characterize any topic. A topic representation can be produced by analyzing a textual description of a topic, or it can be generated from an analysis of documents relevant to a topic. In the latter case, the top content words can be extracted from each of those documents, based on comparing the distribution of term frequencies in the document and the corpus, and these words and their frequencies can be used to represent the topic. As a *Relevant-Term*, the topic-focused summaries can use a *keyword* feature, namely, terms occurring in sentences labeled as highly similar to the topic representation.

Generic summary rule, generated by C4.5Rules learner:
If the sentence is in the conclusion and it is a high tf.idf sentence
Then it is a summary sentence

Topic-focused rule, generated by AQ learner:
If the sentence includes 15..20 keywords
Then it is a summary sentence

Figure 5 Examples of learned rules; from Mani and Bloedorn (1998).

Mani and Bloedorn (1998) compared the performance of generic and topic-focused summarizers constructed using machine-learning methods. They used a corpus of texts in computational linguistics (the *cmp-lg* corpus). The corpus consisted of 198 pairs of full-text sources and author-supplied abstracts (with an average compression of 5%). While the best learners for generic summaries had an accuracy of 67%, the best learners for topic-focused summaries had an accuracy of 90%; this may be attributed to the usefulness of the keyword feature for topic-focused summaries, and points to the relative difficulty of generic summarization compared to topic-focused summarization. **Figure 5** shows some examples of learned rules.

It is possible to formalize the summarization learning problem in terms of a statistical approach to machine translation (MT). The source sentences and summary sentences can be viewed as a (monolingual) parallel corpus. The best summary f for a document d can be represented, as in Equation (3), as the summary s that maximizes the product of two terms: an informativeness (fidelity) term that finds the probability of getting d as a source document for s, and a coherence (well-formedness) term that computes the probability of the summary s (from Berger and Mittal, 2000):

$$f = \underset{s}{\operatorname{argmax}}(P(d|s) \cdot P(s)) \quad (3)$$

Equation (3) allows informativeness and coherence to be traded off. For example, a summary that is a list of keywords may be highly informative, but viewed as incoherent; as more function words and 'glue' text is added to the summary to make it coherent, it may be relatively less informative at a particular

compression. In computing the probabilities in Equation (3), Berger and Mittal (2000) use a bag-of-terms model, e.g., a summary *s* that has more words in common with a document *d* will be preferred. Richer representations than this direct MT approach can clearly be accommodated, for example, based on abstract transfer rules that decompose the mapping from source to summary into a sequence of syntactic tree-transformations (Knight and Marcu, 2000).

Corpus-based approaches to summarization are a very active field of research, in keeping with corpus-based approaches to computational linguistics in general. Even though summarization systems have little grasp of the meaning of the text they are summarizing, progress has been made in recent years in this area. Nevertheless, only a handful of (relatively small) summarization corpora are available at this time.

Improving Summary Coherence Our overall framework for sentence extraction assumes that a draft summary is automatically revised so as to improve coherence. This is in keeping with human abstractors, who, as we mentioned earlier, revise draft summaries. It would be preferable, instead, to take coherence into account earlier in the process, or to trade off informativeness against coherence, as Equation (3) suggests. However, a key problem with automatic summarization is the lack of coherence of the overall summaries, due to dangling anaphors, for example.

To deal with dangling anaphors in a revision phase, one can exclude all sentences that begin with anaphors (possibly sacrificing key summary content), or one can include a window of previous sentences (sacrificing compression), or one can seek to automatically adjust references. Reference adjustment operations include name aliasing (substitution of a proper name with a name alias if the name is mentioned earlier), pronoun expansion (expansion of a pronoun with a co-referential proper name in parentheses), indefinitization (replacement of a definite NP with a co-referential indefinite if the definite occurs without a prior indefinite), and specialization/generalization (replacement of descriptions with more specific/general ones).

These kinds of adjustments presuppose a degree of robust coreference, e.g., of a pronoun and its antecedent (*the dog . . . it*), or proper name or definite NP and its antecedent (*the dog . . . Fido*, *Fido . . . the dog*). While there are a number of methods for establishing co-reference, it is hard to carry out accurately, as it requires a variety of linguistic knowledge sources that interact, including morphological, syntactic, semantic, and discourse information. For generalization/specialization, the use of a thesaurus is required. However, generic thesauri usually have word senses that need to be tuned or augmented so as to be relevant to the domain at hand.

Gaps can be dealt with by simple compression-sacrificing methods, such as including lower-ranked sentences between selected sentences, or including the first sentence of a paragraph if subsequent sentences have been selected. Models based on discourse analysis, while computationally more expensive, can also be used to ensure that the gaps occur only at discourse segment boundaries.

In summary, coherence approaches in sentence extraction tend to occur as an afterthought, and are usually not well integrated into the summarization process. Discourse processing is a major challenge here that needs to be addressed.

Producing Abstracts

As mentioned earlier, an abstract is a summary at least some of whose material is not present in the input, e.g., subject categories, paraphrase of content, etc. Abstracts can involve inferences made about the content of the text; they can reference background concepts, i.e., those not mentioned explicitly in the text. By providing a degree of generalization, abstracts can result in summarization at a much higher degree of compression than extracts. While there are a variety of different methods for producing abstracts, for reasons of space, I will focus here on two kinds of abstracts: cut-and-paste abstracts and template-based abstracts.

Cut-and-Paste Abstracts

I pointed out earlier that professional abstractors use cut-and-paste operations to assemble a summary from material in the source document. Such cut-and-paste operations can be automated (Jing and McKeown, 1999; Mani *et al.*, 1999; Knight and Marcu, 2000). Cutting and pasting operations can be based on a corpus of articles and their corresponding aligned sentences in the articles' abstracts. This provides a probability that a phrase should be eliminated, compressed, or left unchanged. A variety of different cut-and-paste operations have been investigated: reference adjustment (discussed earlier), sentence compression, and sentence aggregation.

Sentence compression involves the lopping off of syntactic constituents, based on one or more criteria, such as the type of constituent, whether it is in a syntactically obligatory role, its cohesion score, its probability of being eliminated, etc.

Sentence aggregation rules add descriptions for people, merge sentences together, and carry out various syntactic smoothing operations. As an example of sentence aggregation, a relative clause introduction

rule turns a VP of a (nonembedded) sentence whose subject is co-referential with an NP of another sentence into a relative clause modifier of the first sentence's NP, e.g., "*the virus, which* ***infected only unclassified computers****, destroyed no data*," where the constituent in bold is pasted in from the source. Other examples of sentence aggregation rules include copying and inserting relative clause modifiers (e.g., *Smith, who* ***first discovered the virus****,*), or appositive modifiers of proper names and definite NPs (e.g., *Peter G. Neumann,* ***a computer security expert familiar with the case*** *...*, *The network,* ***named ARPANET****, is ...*).

Cutting and pasting methods can be used in a variety of different ways. They can be invoked in a revision stage of summarization, where an initial draft summary is constructed and then additional background information from the source is added to it using cut-and-paste operations. In such an approach (Mani *et al.*, 1999), sentences from the source that are highly ranked by the sentence classifier and that describe entities that are also described by sentences in the summary are good candidates for cutting and pasting into the corresponding summary sentences. In an empirical evaluation involving revision of topic-focused summaries, (Mani *et al.*, 1999) show that cutting-and-pasting increases informativeness without compromising readability; the cutting enhances readability, whereas the pasting increases informativeness.

Overall, cut-and-paste abstracts require accurate syntactic parsing, along with discourse analysis; these syntactic operations need to be guided by informativeness measures inferred from a corpus. The necessity of using a corpus to guide the cutting and pasting cannot be overemphasized; arbitrary deletions of constituents, for example, can be misleading and dangerous.

Template-based Abstracts

Template-based abstracts summarize information by filling in slots of templates. The templates are then rendered in natural language. As an example, consider the generation of abstracts for documents on crop agriculture (Paice and Jones, 1993). Table 1 shows the template that their summarizer seeks to instantiate.

The slots are filled by pattern-matching rules. To generate text, canned text templates are used into which names chosen for the slots in Table 1 are inserted. For example, the two canned text templates *This paper studies the effect the pest PEST has on the PROPERTY of SPECIES* and *An experiment in TIME at LOCALITY was undertaken* could produce the abstract *This paper studies the effect the pest G. pallida has on the yield of potato. An experiment in 1985 and 1986 at York, Lincoln and Peterborough, England was undertaken.*

Table 1 Template slots for crop agriculture domain (from Paice and Jones, 1993)

Concept	*Definition*
Species	The crop species concerned
Cultivar	The varieties used
High-level property	The property being investigated, e.g., yield, growth rate
Pest	Any pest that infests the crop
Agent	Chemical or biological agent applied
Influence	e.g., drought, cold, grazing, cultivation system
Locality	Where the study was performed
Time	Years when the study was conducted
Soil	Description of soil

In general, templates used for producing abstracts have been widely used in summarization. Templates can be simple or complex, and several templates may exist for a document (e.g., multi-event templates). Salience is determined based on particular slots, or distance from key concepts in a background concept knowledge base. Recent work in information extraction has developed methods for learning template-filling patterns from annotated corpora as well as expanding seed patterns with information from unannotated corpora. Generation can used canned text, or it can use grammar rules for realizing various linguistic choices (so-called deep generation). Canned text patterns are recommended when there are only a few cases to consider, whereas more complex outputs require the generality of linguistic rules. Generation systems can also avail of corpus statistics in terms of preferring various realizations.

At the same time, templates require customization for specific types of input data, and a template-based summarizer will only work for inputs in a particular domain. Inaccurate template fills can produce inaccurate or nonsensical abstracts, as Paice and Jones (1993) found. The use of deep generation can risk inappropriate lexical choice. For example, in summarizing recommended drug dosage from the medical literature, an abstract that says *high dosage levels are recommended* would be dangerously misleading when summarizing specific dosage levels discussed with various qualifications.

Multidocument Summarization

Multi-document summarization (MDS), as the name indicates, involves summarization of collections of related documents. This is a technology that has become increasingly relevant given the availability of large on-line text collections and the need to condense them. Usually, higher compression rates are required

here, and this is perhaps an area where producing abstracts is more important.

The collections can vary considerably in size, and different methods are suggested for different input sizes; for example, a system might cluster the documents into small sets before summarizing. A naïve extension of single-document summarization based on concatenating single-document summaries of each document is faced with the problem of redundancy, in the form of repetition of information across documents. MDS therefore requires fusion of information across documents.

We can broadly distinguish two classes of approaches. Shallow approaches are based on passage extraction and comparison, with redundancy removed by bag-of-terms–based vocabulary overlap comparisons. The deeper approaches use template extraction and comparison, and carry out syntactic and semantic comparison of passages.

Shallow Approaches

Relevance Versus Redundancy In the case of topic-focused multi-document summarization, there may be multiple text passages that are highly relevant to a topic, but many of these passages may be redundant, containing highly similar information. This sort of problem is endemic in news reports, where similar information is repeated across multiple news sources and over multiple news reports over time. One way of addressing this problem is to explicitly model the redundancy among passages. Consider the case where an initial passage has been found to be highly relevant to a topic. The remaining passages can then be re-ranked so as to maximize their dissimilarity from one seen so far.

This idea can be expressed in a formula for maximal marginal relevance (MMR) (Carbonell *et al.*, 1997). MMR is defined in Equation (4), where Q is the topic (or a key passage, in the case of a generic summary), R is the relevant set of passages, S is the scanned subset of R (i.e., the passages already included in the summary), and $R \backslash S$ is what is left of R once S is removed. When λ is zero, the maximally diverse ranking of passages is obtained; when λ is 1, relevance to topic alone determines the ranking of documents. The setting of λ is, in general, left to the application.

$$MMR(Q, R, S) = \underset{D_i \in R \backslash S}{\operatorname{argmax}}(\lambda\, sim_1(D_i, Q) - (1-\lambda) \max_{D_j \in R} sim_2(D_i, D_j)) \qquad (4)$$

Cohesion-based Models The cohesion-based approaches discussed earlier can also be applied to MDS. As shown in Figure 3, paragraphs that are connected to many other paragraphs with a similarity above a particular threshold are considered salient, since they would very likely contain topics discussed in many other paragraphs. Salton *et al.* (1997) discuss such graphs constructed based on similarity of passages across documents.

More fine-grained approaches to cohesion that rely on word-level links can also be applied, e.g., with the nodes being term occurrences in the text and the links being relations of co-reference, synonymy and hypernymy. Instead of directly comparing the two cohesion graphs, which is computationally very expensive, the most important regions of each graph can be found by propagating salience information across the graph. The highly weighted regions of each graph can then be compared across texts to find out commonalities and differences. The comparison method looks up the words in the highly weighted regions and intersects them across documents, building a set of **Common** topic-focused terms. The terms in highly weighted regions in each document that are not in **Common**, are topic-focused terms **Unique** to each document. The most heavily weighted sentences in **Common** (or *Unique*) can be presented as a summary of commonalities (or differences).

Alternatively, pairs of sentences can be aligned based on similarity of terms covered in **Common**. Figure 6 shows aligned sentence pairs from two documents.

Application: Biographical Summarization The possibility of a program trolling through a large corpus gathering important information about people or other entities offers interesting opportunities for multi-document summarization. Figure 7 shows a three-sentence summary of information about the person Vernon Jordan, summarized automatically by a biographical summarizer from a collection of 1300 news documents.

The biographical summarizer finds 607 sentences which mention *Jordan* as a person name; 78 appositive phrases describing Vernon Jordan that fall (using a thesaurus) into two semantic groups: *friend* and *adviser*; 65 sentences with *Jordan* as logical subject, filtered based on verbs that are strongly associated in a background corpus with the deep subjects *friend* or *adviser*, e.g., the verbs *testify, plead, greet*. Note that there is still a degree of redundancy between *presidential friend* and *Clinton adviser,* but the program is not able to detect that.

Overall, the shallow approaches to MDS are able to home in on common content, characterizing and (especially in the case of MMR) eliminating redundancy. They are also able to achieve high levels

Figure 6 Commonalities across pairs of documents; from Mani (2001), with permission.

of compression. They are unable, however, to characterize the nature of differences in content, or to accurately distinguish between events occurring at different times or places.

Deep Approaches

I will discuss two approaches here. The first tries to merge information by considering paraphrases. The second compares and merges templates.

Paraphrasing As mentioned earlier, a system might first cluster a large collection of documents to be summarized into smaller sets of documents. However, a shallow MDS approach that would extract representative sentences from each cluster could contain information that is not common across all sentences in the cluster. A more fine-grained approach is needed to represent common content. Barzilay *et al.* (1999) describe some of the methods used within the Newsblaster system shown in Figure 1. Their approach intersects sentences in the cluster to identify phrases common across a majority of paragraphs in the cluster. This intersection operation is carried out by first parsing the sentences, then comparing the parse trees based on paraphrasing rules. These rules include active versus passive forms, classifier versus appositive expressions, e.g., *Pentagon speaker* and *speaker from the Pentagon*, etc. Rather than simply listing the set of cluster intersection strings, a sentence generator is invoked to combine their associated trees to yield a sentence. Thus, the clause *McVeigh was formally charged on Friday with the bombing* and the phrase *Timothy James McVeigh, 27*," would be fused together using cut-and-paste methods to yield *Timothy James McVeigh, 27, was formally charged on Friday with the bombing*." Such paraphrasing rules involve deeper knowledge, as they reference both syntactic and semantic information.

Template Comparison Template-based methods for producing extracts can be naturally extended to multi-document summarization. Templates filled

Vernon Jordan is a presidential friend and a Clinton adviser. He helped Ms. Lewinsky find a job. He testified that Ms. Monica Lewinsky said that she had conversations with the president, that she talked to the president.

Figure 7 A three-sentence biographical summary from 1300 documents; from Schiffman *et al.* (2000).

The afternoon of Feb 26, 1993, Reuters reported that a suspected bomb killed at least five people in the World Trade Center. However, Associated Press announced that exactly five people were killed in the blast.

Figure 8 A multi-document summary based on a contradiction operator; from Radev and McKeown (1998).

from each document in the collection can be compared, with differences between the documents being characterized in terms of template comparisons. Discrepancies between template fills can arise, depending on a variety of factors. For example, in the case of news reports, information may arise at different times, and earlier information may be corrected in a later report; otherwise, differences may be due to different points of view on an event. Consider a template for terrorism events, one that lists the perpetrator, victim, type of event, location, dates, etc. Templates that have the same incident location but that originate from different sources and have one other slot in the template differing in value across the documents can be considered as expressing a contradiction.

The work of Radev and McKeown (1998) defines various text-structuring operators. Each operator takes a pair of templates and yields a more salient merged template. The contradiction operator applies to the above case of a contradiction, using a variety of heuristics to resolve the contradiction. For example, the value of the number of victims can be lowered across two reports from the same source, suggesting that the old information is incorrect; if it goes up, the first report had incomplete information. Finally, the most salient merged templates are chosen for realization using natural language generation. Here each template maps no more than one paragraph, to help control compression. Figure 8 shows an example output.

Summarization Evaluation

Evaluation of summarization evaluation has always been a challenging problem, for several reasons:

- There might not be a unique correct answer in terms of the correct summary. There is always the possibility of a system generating a good summary that is quite different from any human reference summary used as an approximation to the correct output. Summarization is similar, in this respect, to other output technologies such as machine translation and speech synthesis.
- Humans asked to summarize texts show little agreement with each other, as shown below.
- Since humans may be required to judge the system's output, this may greatly increase the expense of an evaluation. An evaluation that could use a scoring program instead of human judgments is preferable, since it is easily repeatable, allowing machines to be trained to improve the score.
- It is important to be able to evaluate summaries at different compression rates. An evaluation at 5% compression may reveal very different results from one at 25%. This increases the complexity of the evaluation.

As will be shown, these problems can all be addressed in part. There are two classes of evaluation methods that can be considered for summarization (as well as for natural language processing systems in general): intrinsic and extrinsic methods. Intrinsic methods test the system in itself, in this case, as a summarizer. Extrinsic methods test the summarizer in the context of some other task, such as information retrieval, question answering, database filling, etc.

Intrinsic Methods

In intrinsic methods, both coherence and informativeness can be tested. **Coherence** can be judged by subjective grading (e.g., a 1–3 scale) on specific criteria, such as grammar, style, conciseness, understandability, acronym expansion, etc. Criteria can also be tailored specifically to extracts (dangling anaphors, gaps, etc.) or abstracts (ill-formed sentences, inappropriate lexical choices, etc.). Automatic scoring has a limited role to play here, though more recent grammar checking tools may be useful.

Informativeness measures the extent to which a summary preserves information from a source or a reference summary. Therefore, one measure of the informativeness of a summary is the assessment of how much information from the source is preserved in the summary. Another informativeness measure is how much information from a reference summary is covered by information in the system summary. I shall discuss this below. Usually, system summaries are compared for informativeness against some baseline, as well as in comparison with humans; here agreement among humans is taken as an upper limit on summarization accuracy. I now turn to the issue of agreement among humans in summarization.

Factors Influencing Summary Variability When a subject is given specific instructions on how to construct a summary, the space of possible summaries is constrained by such instructions. The human summary may be supplied by a document's author, or by a subject asked to construct an abstract or extract. When a subject is used to construct a reference extract, she may be required to judge every sentence for summary-worthiness. Alternatively, the subject may be told to pick the top c% of the sentences in the document. Or, the subject may be told to rank all (or the top c% of) the sentences in the document; such instructions really produce sentence rankings rather than summaries *per se*. Note that the subject may be required to extract clauses or paragraphs, or arbitrary-sized passages, instead of sentences. Alternatively, instead of an extract, the subject might be asked to produce an abstract, with various instructions as to how those abstracts should be constrained in terms of compression rate, target length, coverage, etc. The different compression instructions can make a considerable difference in the quality and consistency of the resulting summaries.

Studies of Human Agreement Previous studies, most of which have focused on extracts, have shown evidence of low agreement among humans as to which sentences are good summary sentences. Rath *et al.* (1961) found that subjects asked to extract 20 sentences from each of 10 *Scientific American* articles agreed with each other only 8% of the time. Salton *et al.* (1997) found that two subjects showed only 46% overlap in their extracts when asked to extract at least five paragraphs from each of 50 articles from an encyclopedia. However, there is also evidence that judges may agree more on the most important sentences to include.

When subjects disagree, a system can be compared against majority opinion, most similar human summary (optimistic) or least similar human summary (pessimistic) (Salton *et al.*, 1997). Another possibility is to compare the system summary against a pool of alternative reference summaries collectively treated as a single reference summary.

Measuring Informativeness Measurements of informativeness can use subjective grading in terms of specific criteria, but it is more common to measure sentence recall, namely how many of the reference summary sentences the system summary contains. For example, if a reference summary has 10 sentences, and the system summary got four of them, recall would be 0.4. Sentence precision can also be measured, namely the number of reference summary sentences in the system summary. Thus, if the system summary had 20 sentences, and four of them were in the reference summary, the precision would be 0.2. (Note that when the reference and system summaries are of the same length, sentence precision is equal to sentence recall.) Sentence recall and precision are mainly applicable to sentence extracts, not abstracts. However, a sentence recall measure is not sensitive enough, since for a summary n sentences long it can distinguish between only $n+1$ scores, allowing summaries that are quite different in content to be given the same scores (Donaway *et al.*, 2000).

Content-based similarity measures based on bag-of-terms overlap can work on both extracts and abstracts. These bag-of-terms measures can be enriched by comparisons of longer terms, and they can be useful for comparing extracts. The disadvantage is that they do not discriminate very well between summaries that involve differences in meaning expressed by synonymy, hypernymy, negation, word ordering, paraphrasing, etc. that may arise, especially in the case of abstracts. An alternative is to compare system and reference summaries based on the atomic propositions (semantic content) that are common to them. However, automating such an approach is a challenge, in part because of the many different ways a core proposition can be expressed in natural language.

The SUMMAC text summarization evaluation Question and Answer task (Mani *et al.*, 2002) used a recall measure tailored to topic-focused summaries. Given a document and a topic, the idea is that an accurate topic-focused summary of the document would contain answers to questions that cover obligatory information that needs to be present in any document judged relevant to the topic. For example, a document relevant to prison overcrowding might contain an answer to a question about the names of prisons involved. Given the source document with answers to such topic questions marked up, the humans judged the summary in terms of recall of the marked-up answers (i.e., answer recall). Mani *et al.* (2002) discovered an informativeness ratio of answer-recall accuracy to compression of about 1.5.

The Document Understanding Conference (Over and Yen, 2004) has conducted evaluations of single and multi-document summarizers since 2001, based on comparisons against reference summaries. The 2003 evaluation defined four tasks: the first one was a very short (10-word) single-document summary, called the headline task. The other three tasks involved topic-focused multi-document summaries. System summaries were presented side-by-side with reference summaries in an interactive tool. System summaries were judged for coherence based on subjective grading on various criteria. To assess informativeness, the judges were asked, for each elementary

discourse unit in the reference summary, to mark one or more units in the system summary that covered the same content as the reference summary unit, with the extent of coverage being defined by a five-point scale. The systems were judged less informative than human summaries on all the tasks, with most systems being indistinguishable from one another. The results also indicate, in keeping with prior research, that in news articles, using a summary baseline of the leading sentences is often hard to beat. This is because many news stories are written with an inverted pyramid structure, with the latest and most important information presented first.

Automatic Scoring The SUMMAC Question Answering task developed an automatic scoring program that measured the content similarity between system and the marked up answers in reference summaries using four different bag-of-terms overlap measures. The correlation between system rankings on these latter measures and those on the human-assigned answer-recall measures was very high. More recently, Lin and Hovy (2003) developed a recall measure inspired by recent work on machine translation evaluation. Instead of doing bag-of-terms comparisons, the scorer compares words (unigrams), pairs of words (bigrams), trigrams, and quadrigrams (and combinations) in common, along with a bonus based on how short the system summary is. It was found that the system rankings based on unigrams correlated well with the informativeness measures of DUC judges. Longer *n*-grams did not yield such a result, perhaps because the reference summaries involved summaries in the abstractors' own words, resulting in fewer phrases in common with the mainly extractive system summaries.

Extrinsic Methods

The idea of an extrinsic summarization evaluation is to determine the effect of summarization on some other task. The variety of tasks to which summarization can be applied is in fact very large, and will expand as computer technology continues to evolve. I will first illustrate several example tasks here:

If the summary involves instructions of some kind, it is possible to measure the efficiency in executing the instructions. A summary can also be assessed for usefulness with respect to some information need or goal, such as finding documents relevant to one's need from a large collection, routing documents, producing an effective report or presentation using a summary, etc. When a summarizer is embedded in a larger system, such as a system for question-answering, it is possible to test how much the question-answerer is improved through the use of summarization. When a summary has to be used in preparation of a report, one can measure the amount of effort required to post-edit the summary.

Relevance Assessment In relevance assessment, a subject is presented with a document (retrieved by a search engine) and a topic, and asked to determine the relevance of the document to the topic. There have been a number of studies of the influence of summarization on accuracy and time in relevance assessment. The SUMMAC evaluation (Mani *et al.*, 2002) provided relevance assessment by 51 subjects of the output of 16 summarization systems that carried out single-document summaries of news articles. Results showed that summaries at relatively low compression rates (generic summaries at 10% of source length, and topic-focused summaries as short as 17% of source length) reduced relevance assessment time by 40% (for generic summaries) to 5% (for topic-related summaries), with no statistically significant degradation in accuracy. Systems that performed most accurately in the production of topic-focused summaries used statistical methods involving term frequency and term co-occurrence statistics, and vocabulary overlap comparisons between text passages; they extracted similar sets of sentences. However, for generic summaries, the systems (which relied in this case on inclusion of the first sentence of the news article) were indistinguishable in accuracy.

One limitation in this evaluation (and many others) is the restriction of the genre to newswire texts, and the fact that such a task could be addressed by extracts, without requiring abstracts.

Reading Comprehension Another interesting paradigm for extrinsic evaluation is in reading comprehension. Here the subject first reads source documents or summaries and then answers multiple-choice tests, which are then automatically scored against an answer key. Morris *et al.* (1992) used four Graduate Management Admission Test (GMAT) reading comprehension exercises. They measured how many of the answers the subjects got correct under different conditions, including a full-text condition (where the subjects were shown the original passages), an extract condition (where the subjects were shown automatically generated 20% and 30% generic extracts from the passages, based on either Edmundson's method or random sentence selection), an abstract condition (where the subjects were shown a generic human abstract of about 25% compression created by a professional abstractor instructed to create informative abstracts), and a control no-text condition (where the subjects had to pick the correct answer just from seeing the questions, without seeing the

passages themselves). The results showed that the performance of the extracts based on Edmundson's method as well as the informative abstracts were comparable to the full-text condition, with the random and no-text conditions being significantly below the full-text performance. However, the number of exercises in this study was very small, and the exercises being summarized tended to be very short.

Intrinsic Versus Extrinsic Methods

The choice of an intrinsic or extrinsic method depends on the goals of the developers, funders, and consumers of the summarization technology. In general, at early stages of the technology cycle, intrinsic evaluations are recommended, with an emphasis on evaluation of summarization components; as the technology matures, task-based tests of the system involving real users become more important. Extrinsic evaluations have the advantage of assessing the utility of summarization in a task, so they can be of tremendous practical value to a funder or consumer of summarization technology. However, they are less useful to developers in terms of offering feedback as to how they might improve their systems. This can be somewhat alleviated when a system's performance in an intrinsic evaluation predicts performance in an extrinsic one.

New Areas

Multimedia and Multimodal Summarization

As we move into the vast information universes of the 21st century, summarization of some kind becomes indispensable as a method of managing information. Increasing quantities of multimedia information are becoming available for online access. The ability to summarize the content of imagery, video, and audio along with text is thus very crucial. New genres of communication are becoming widespread, including the use of e-mail and chat. The transcripts of a variety of dialogues are being recorded, including telephone conversations, meetings, etc. The linguistic analysis of these different genres and information sources is of considerable interest. At the same time, multimedia interfaces are increasingly used for communication, along with handheld devices such as cell phones and personal digital assistants (PDAs). The study of the human–computer interfaces in such systems is also of growing interest.

Summarization in such environments can be extremely powerful. For example, a multi-document summarizer that examines both databases and news sources to report the latest developments in weather, agricultural prices, or other such topics in very short text or spoken messages or a map display for a cell phone could be extremely valuable to people in different communities around the world. The techniques for text summarization we have discussed here are broadly applicable to multimedia summarization as well, though the particular features depend on the media and genre. Systems today can summarize TV news broadcasts as well as meeting dialogues and telephone conversations.

However, the effectiveness of summarization in such applications depends on progress toward accurate audio, image, and video understanding. These latter areas still lag behind text understanding.

Summarizers have also been used in displays on PDAs and cell phones (here, topic-focused summaries and fragment output is often preferred). In addition, they have been tailored for cell phone output, where, for example, short sentences without proper names are preferred for more understandable speech output. Summarization in such environments requires an adequate linguistic characterization of the relevant genres and communication modes.

Narrative Summarization

The success of summarization is predicated on adequately capturing information content. An ability to do this can avoid inappropriate content selection as well as summary incoherence. Getting a machine to understand and summarize human narratives has been a classic challenge for both natural language understanding and artificial intelligence. Central to all narratives is the notion of time and the unfolding of events (chronologies), as well as the global discourse structure of the narrative and the emotional significance of various outcomes. Research in this area has begun creating corpora with manual and automatic annotation of events and their temporal anchoring (i.e., when the events occur), as well as aspects of the discourse structure of narratives. These research efforts should allow summarizers to create timelines summarizing information about one or more entities in a document collection over time, as well as summarize different threads of a story.

There has been considerable progress in temporal information processing, and research on discourse models of narrative has been an active field within linguistics. Systems that process this kind of information are able to deal with implicit information (temporal anchors and markers of narrative structure are often missing) as well as vagueness (e.g., *recently*, *last summer*). The understanding of spatial references is, however, somewhat less developed than

that of temporal reference. Plot understanding has not been successfully addressed, with the solutions developed to date being highly domain-specific as well as inefficient. These areas offer challenges to future research.

Conclusion

Automatic summarization is an active field with many interesting problems. The basic frameworks for summarization of extracts and abstracts have been well established and explored over the last four decades. There are several areas where capabilities need to be improved:

- Further studies of human abstracts and abstractors, as well as the analysis of large corpora of source texts and their summaries, are needed to stimulate further progress. Here, the quality of the abstracts, and consistency of guidelines used by abstractors are critical.
- Summarization evaluation needs to be explored much more. The field has been limited by an inordinate amount of attention being paid to the summarization of news, where it has been found that forming a baseline summary from the leading sentences of a news article has been hard to beat. Further progress in evaluation can come from the study of other genres, including scientific text, legal text, e-mail, chat, etc.
- Improved linguistic characterizations of different genres of text is needed, along with techniques for automatically interpreting information about these genres. Developing genre-specific discourse models, for example, is likely to result in major advances.

Overall, the extraordinary developments in information technology and the vast information horizons of the future make summarization a very valuable and engaging research area.

Summer Institute of Linguistics

P Frank, SIL International, Dallas, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

SIL International is a faith-based organization that studies, documents, and assists in developing the world's lesser-known languages. SIL's work contributes to the well-being of the peoples whose languages it helps develop and to the national and international understanding of the richness of human languages. The organization works in partnership with governments, nongovernmental organizations, universities, and local communities. SIL's staff share a Christian commitment to service, academic excellence, and professional engagement. SIL makes its services available to all without regard to religious belief, political ideology, gender, race, or ethnic background.

SIL (formerly known as the Summer Institute of Linguistics) began as a small summer linguistics training program in 1934 with two students (see **Figure 1**). Its linguistic investigation now exceeds 1800 languages, spoken by over 1.2 billion people in more than 70 countries, with staff from more than 60 countries.

History

The organization began from William Cameron Townsend's concern and vision for people in lesser-known language groups. Townsend worked cross-culturally in a Mayan village in Guatemala, learned Cakchiquel, carried out educational and development work, and promoted Bible translation (see **Figure 2**). After years in Guatemala, he expanded his concern to include the many other linguistic-minority peoples of the world. SIL was founded in 1942 and promoted his philosophy of 'threefold service': to serve others scientifically, materially, and spiritually.

SIL International is a faith-based organization that studies, documents, and assists in developing the world's lesser-known languages. SIL's work contributes to the well-being of the peoples whose languages it helps develop and to the national and international understanding of the richness of human languages. The organization works in partnership with governments, nongovernmental organizations, universities, and local communities. SIL's staff share a Christian commitment to service, academic excellence, and professional engagement. SIL makes its services available to all without regard to religious belief, political ideology, gender, race, or ethnic background.

SIL (formerly known as the Summer Institute of Linguistics) began as a small summer linguistics training program in 1934 with two students (see Figure 1). Its linguistic investigation now exceeds 1800 languages, spoken by over 1.2 billion people in more than 70 countries, with staff from more than 60 countries.

History

The organization began from William Cameron Townsend's concern and vision for people in lesser-known language groups. Townsend worked cross-culturally in a Mayan village in Guatemala, learned Cakchiquel, carried out educational and development work, and promoted Bible translation (see Figure 2). After years in Guatemala, he expanded his concern to include the many other linguistic-minority peoples of the world. SIL was founded in 1942 and promoted his philosophy of 'threefold service': to serve others scientifically, materially, and spiritually.

Figure 2 Cameron Townsend and his wife Elvira in front of their village house in Guatemala. © SIL International. Reproduced with permission.

Figure 3 Kenneth L. Pike. Photo by Angela Carlson. © SIL International. Reproduced with permission.

Ken Pike was one of the early leaders of SIL and became one of SIL's best-known members (see Figure 3). Pike developed the terms 'etic' and 'emic,' which have since become foundational concepts in linguistics and anthropology. Over the course of 65 years he published 258 articles and books.

Partnership

SIL works with many government agencies and academic institutions around the world. One key international partnership is with UNESCO. UNESCO granted consultative status to SIL in 1992, and in 1997 SIL was granted special consultative status with the United Nations through the Economic and Social Council. In 1998 SIL was admitted into formal consultative relations with UNESCO (see Figure 4).

Personnel

SIL's staff come from more than 60 countries. Each staff member is motivated and unified by the belief

Figure 4 John Watters, SIL Executive Director (left) and Koichiro Matsuura, Director-General, UNESCO. © SIL International. Reproduced with permission.

that every person is created in the image of God and has value and dignity. Understanding and respect are basic in every effort, whether at the local community level or with the national government. SIL workers seek to build partnerships for development in such individual specialties as linguistics, language survey, literacy, translation, training, and practical community help.

Languages

SIL focuses primarily on unwritten and under-documented languages. The people who speak these languages are often marginalized from national life, in geographic, social, and economic isolation and disadvantage. The study of these languages gives practical help to the local people and also contributes to broader knowledge in academic disciplines such as linguistics, anthropology, and ethnomusicology. SIL is committed to publishing its academic research by widely distributing the results on the Internet and to libraries, universities, governments, and international agencies.

SIL is a leader in the study of the world's endangered languages through language survey and documentation. Where possible, SIL facilitates language development to prevent the extinction of languages and cultures. SIL's premier publication, *Ethnologue*, is a comprehensive catalog of the more than 6900 living languages in the world (see Figure 5).

Language Technology

SIL provides resources to help field workers organize and analyze language and culture data and prepare the results for publication. These resources include software (see Figure 6) and fonts, the LinguaLinks resource library, and other textbooks and publications.

SIL's Non Roman Script Initiative is a research and development team whose mission is to provide guidance, information, and research and development to facilitate the use of non-Roman and complex scripts in linguistic study, translation, literacy, and publishing. SIL is collaborating with UNESCO in their Initiative B@bel with the goal of helping protect languages in danger of disappearing and promoting multilingualism on the Internet.

Literacy

The ability to read is not an isolated intellectual skill; it is the key to personal, local, and national development. Literacy in SIL distinctively focuses on developing programs in lesser-known and endangered languages and emphasizes using the mother tongue as the gateway to basic literacy. SIL's vision is to see literacy become a sustainable community value with the ownership of literacy goals and activities in the hands of the people.

SIL also assists local, regional, and national agencies that are developing formal and informal

Figure 5 *Ethnologue*, available online at www.ethnologue.com. © SIL International. Reproduced with permission.

Figure 6 The Speech Analyzer program for acoustic analysis. © SIL International. Reproduced with permission.

education in vernacular languages. Such cooperation promotes multilingual education and enables new advances in the complex field of educational development in multilingual and multicultural societies.

Translation

In many parts of the world, SIL works in partnership with local speakers to adapt or translate literature for publication on nutrition, farming, health (including HIV/AIDS) (see Figure 7), and some or all of the Bible (see Figure 8). SIL's involvement and the scripture translation goals for each language are decided in close interaction with church and community leaders and other partnership groups or organizations.

Training

SIL, in partnership with institutions and organizations worldwide, offers training for applied linguistic fieldwork at more than 20 locations in North and South America, Europe, Africa, Asia, and Australia. Topics for courses include phonetics, phonology, grammar, language learning, linguistic field methods, cultural anthropology, sociolinguistics, literacy, translation, and language program planning. Classes are taught by professional staff with a broad range of field experience and a commitment to high academic standards. Graduates of these training programs are working on six continents, serving as SIL staff or in partner organizations. In addition, SIL staff conduct workshops within communities to train local leaders in language-related topics, enabling them to become trainers themselves (see Figure 9). The local language is used as the medium of instruction whenever applicable.

Figure 8 An SIL worker and local colleagues translating the Bible into a language of Cameroon. © SIL International. Reproduced with permission.

Community Service

One of SIL's goals is people-centered development. For that reason the organization gives priority to training local people in ways that help them develop their full potential. SIL also integrates language and literacy skills with other forms of community development. The development of written materials on health care, agriculture, spiritual growth, sanitation, and other topics requested by local communities is combined with practical training.

Funding

Resources for the work of SIL are provided primarily by affiliated organizations in various parts of the world. Major contributors include member organizations of Wycliffe International, which have the goal of promoting the translation of Christian scripture into the world's languages where appropriate. Grants from private corporations and foundations as well as funding from various government agencies have assisted SIL in its literacy and other related projects. In addition, most SIL workers develop individual funding resources for particular projects and personal support.

Vision for the Future

SIL's greatest contribution in the future will be building capacity for language development at local, national, and international levels. Research, resources, training, and facilitation will be the hallmarks of SIL's involvement worldwide. SIL does not have the capacity to directly impact all of the world's minority groups where language development is needed. Empowering speakers of these languages is fundamental but must be complemented by service to governments (particularly with regard to bilingual and multilingual education), fostering and equipping of nongovernmental organizations, and advocacy for minority language development in the international arena, where fundamental polices are formed that impact national legislation and practice (see Figure 10). Last, foundational

research in language-related disciplines and documentation of languages will continue as SIL's core contributions in the 21st century.

Acknowledgments

SIL International kindly granted access to various documents describing aspects of the organization's work and other resources that have been included in this article.

Suppletion

G Boyé, Université Nancy 2/ATILF, Nancy, France

© 2006 Elsevier Ltd. All rights reserved.

The term 'suppletion' is used to describe two distinct but related phenomena. In its original use, suppletion designates the diachronic process by which the inflectional paradigms of two unrelated words are fused to give rise to a new word with a mixed paradigm. This is what happened, for example, when the Old English verbs *gān* 'to go' and *wend* 'to turn' mixed their paradigms to give rise to the modern *go* with the *go/went* alternation. In more recent literature, suppletion is often used to describe a type of allomorphy, where some forms of a word are based on different stems that are not synchronically related.

Note that suppletion in the first sense is one of the factors that can give rise to suppletion in the second sense, but that there is no one-one relationship; a paradigm may become synchronically suppletive because of the loss of some productive phonological alternation, in which case it is not suppletive in the diachronic sense. In the remainder of this article, we concentrate on suppletion in the more recent, synchronic sense.

The Types of Suppletion

The most common variety of suppletion is 'stem suppletion': the inflectional paradigm is split in areas containing inflectional forms based on the same stem. In each area, the forms of the word appear with the usual inflectional affix, but the stem is different from one area to the next. In French, for instance, the irregular verb *aller* 'to go' uses the stem *i* for the future and the conditional (FUT 1SG *i-rai*, 2SG *i-ras*, 3SG *i-ra*, etc.) but the stem *aille* for present subjunctive singular (1SG *aille*, 2SG *aille-s*, 3SG *aille*), presenting a suppletive alternation, where a regular verb like *aimer* uses the stem *aime* for both areas (FUT 1SG *aime-rai*, 2SG *aime-ras*, 3SG *aime-ra*, etc.; SUBJ 1SG *aime*, 2SG *aime-s*, 3SG *aime*).

In some cases, suppletion can target an isolated form such as the English present 3SG form *is* in the paradigm of *be*. In this particular case, the inflectional form could be analyzed as a suppletive stem *i* followed by the present 3rd singular affix *s*. But an isolated suppletive form can also resist analysis in terms of stem and inflectional affix: in Spanish, even though the 1SG of the present indicative is uniformly marked by a final *–o* (*–oy* for monosyllabic verbs), the verb *saber* 'to know' displays a suppletive form *sé* without the suffix *–o*. This form cannot be decomposed into a suppletive stem and a regular affix; the entire form is suppletive. This type of irregularity can be described as 'inflectional form suppletion.'

Suppletion is usually considered to be an inflectional phenomenon because it presupposes the presence of a paradigm in which the suppletion takes place. Nevertheless, suppletive stems can also be found in word formation. In Latin, for example, the deverbal noun ending in *-or* derived from *ferre* 'to bear' is *lator*. This is formed on its suppletive 3rd stem *lat-*, which is also used to build *latum*, the supine form of *ferre* (an inflectional form). In this example, suppletion occurs in word formation as well as in inflection. In this light, stem alternations such as *Glasgow/Glaswegian* or *Indiana/Hoosier* could be contrived as stem suppletion; however, without an inflectional paradigm, the distinction between suppletion and synonymy is difficult to define: *Australia/Aussie* is parallel to the previous pairs while *Aussie* is merely a synonym of the nonsuppletive *Australian*.

Linguists considering affixes as signs also apply the concept of suppletion to inflectional or derivational affixes. For inflection, in English, the regular inflectional affix for plural is *-s* (*cat/cats*) while some plurals are formed with the suffix *-en* (*ox/oxen*). For word formation, in French, inhabitant names are derived from the city names through different suffixes (*-ien*: *Paris* → *parisien*, *-ais*: *Marseille* → *marseillais*, *-ois*: *Lille* → *lillois*, *-ain*: *Toulouse* → *toulousain*, etc.). These suffixes could be analyzed as suppletive allomorphs of a single morpheme.

Suppletion and Stem Allomorphy

Among cases of stem allomorphy, suppletion is the extreme case where no synchronic relation can be found between the allomorphs. Alternatively, some stem allomorphies can be reduced to phonological alternations. In German, word final obstruents are devoiced creating predictable allomorphies in the paradigm of nouns *Tag* [tak] 'day,' *Tage* [tagə] 'days.'

Linguists disagree about the adequate description of intermediary cases where the stems are phonologically similar, but no productive phonological rule can account for the alternation. At one end of the spectrum, some linguists propose that all variations of shape (*feel/felt*, *make/made*, *ring/rang*, etc.), should be considered rule-governed allomorphies, and only the cases of complete dissimilarity (*go/went*, *be/were*) should be considered suppletive (Chomsky and Halle, 1968). At the other end, others make no distinction between nonpredictable allomorphies, and treat all irregularities in the same way (Pinker, 1999). This amounts to treating alternations such as *make/made*

as suppletive. Under such a view, suppletion has nothing to do with phonological dissimilarity. It may even be argued that two identical stems can enter a suppletive relation: the irregularity of an English verb like *cut* resides precisely in the absence of change between present and preterite (*cut/cut* and not *cut/cutted*).

Suppletive Stems and Exponence

In inflectional paradigms, suppletion typically targets a natural class of forms associated with a morphosyntactic or morphophonological property. The selected class usually involves the most salient semantic contrast with the rest of the paradigm (Bybee, 1985). Veselinova (2003) showed that this kind of split occurs mainly in terms of tense/aspect, suppletive imperatives, or verb number. There seems to be some bias in the distribution of this typical stem suppletion in terms of genetic (suppletive imperatives in Afroasiatic and Caucasian languages) and areal (tense/aspect in Europe and verb number in North America) groupings. As the split involves natural classes, this leads to considering the stems with marked exponence as suppletive and unmarked as the base.

However, some languages (20%, mostly concentrated in Europe according to Veselinova) exhibit stem suppletion where some sets of forms associated with a suppletive stem do not constitute a natural class in term of semantic, syntaxic or phonological features. In Spanish, for example, the description of the verb *hacer* 'to do' needs two stems for sets of forms without clear common properties: *haga* for the present subjunctive and the present indicative 1st singular; and *hace* for the rest of present indicative, the imperfective, the imperative, the infinitive, and the gerund.

To describe this kind of stem suppletion, Aronoff (1994) proposed to consider these types of stems as forms without meaning, 'morphomes.' The morphomes are purely morphological objects: phonological sequences without associated semantic or syntaxic features, indexed to appear in specific paradigm zones.

The Distribution of Suppletive Stems

If suppletion were a random phenomenon, it should be possible that stem suppletion targets completely different sets of inflectional forms for different words giving rise to a large number of irregular inflection patterns. However, irregular inflection patterns are usually a lot less varied than is *a priori* conceivable.

This limitation of suppletion has long been recognized for languages with rich inflectional morphology. The paradigm of an irregular word is usually described by giving its 'principal parts': a set of forms sufficient to identify suppletive stems and infer the rest of the paradigm (e.g., in Latin, *fero, ferre*, *tuli*, and *latum* are the principal parts of *ferre* 'to bear'). Manuals for teaching English as a foreign language all use the plain form, the preterite and the past participle as the principal parts of a verb (setting apart auxiliaries and modals). Descriptions using principal parts suggest that verbs uniformly use the same stem in definite zones of the paradigm. Thus conjugation can be, described by associating each verb with a collection of stem slots corresponding to these zones. Suppletion is then limited to the use of distinct stems for each slot.

In French, all suppletion patterns in verbs can be described using 12 stem slots, but massive gaps in the suppletion patterns are observed (less than 0.01% of possible patterns actually exist). Even though, for instance, three slots are needed to describe the present indicative ($Slot_1$: singular; $Slot_2$: 3rd plural; $Slot_3$: 1st and 2nd plural), no French verb exhibits the same stem in $Slot_1$ and $Slot_3$ while presenting a different stem in $Slot_2$. Bonami and Boyé (2003) proposed that these gaps in the suppletion patterns are the result of a further organization of the stem slots by a network of default relations. Each idiosyncratic stem occupies a connected territory in the network.

The Causes of Suppletion

As with irregularity in general, token frequency is an important factor favoring suppletion. On the one hand, suppletion being an idiosyncrasy, it needs to be memorized; a language learner needs to be sufficiently exposed to the suppletive forms to be able to detect them and store them. On the other hand, the words appearing most frequently are the most likely to become irregular.

Suppletion is thought to happen in two contexts: etymological suppletion, when two distinct words with similar meanings come to be used in the same sense but for different parts of the inflectional paradigm, while the rest of their paradigms drops in frequency, creating the impression of a unique word being used; and nonetymological suppletion, when a regular phonological alternation dies away and is reanalyzed as allomorphic alternation, and in turn as suppletive alternation.

Maiden (1992) showed that some cases of nonetymological suppletion were not the product of the reinterpretation of a phonological alternation but that of a novel allomorphy. In Old Italian, stem-invariant verbs such as *fuggire* 'to flee' were subjected to allomorphic alternation based on a proportional analogy with *leggere* 'to read.' In his observation of

Romance languages, novel allomorphies seem to be correlated with stem slots. The same slots seem to be also used in etymological suppletion, and both types of suppletion appear to involve a high degree of solidarity between the inflectional forms based on the same slot.

Suriname: Language Situation

E B Carlin, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Suriname (population about 440 000) is a country with enormous wealth, in terms of both natural resources and languages. The official language of the state is Dutch, which is a reflection of the fact that from 1667 until 1975 Suriname was a Dutch colony; and also of the fact that roughly 300 000 people of Surinamese descent live in the Netherlands (and thus are predominantly Dutch-speaking). Traffic between the two states by the Surinamese is constant and regular. In total, Suriname is home to 19 languages spoken by communities of different sizes who see themselves as a political, ethnic, or cultural unit, and who have Surinamese nationality and most of whom have representation of some kind in the political and economic sphere. These languages fall into three main categories: (1) indigenous Amerindian languages (**Figure 1**); (2) English-based creole languages; and (3) Eurasian languages that were imported from Europe and Asia. The following overview gives each of the languages followed by two numbers in parenthesis: first the size of the ethnic group (E), then the number of speakers (S); where these coincide, only one number is given. The location of the rural groups is given on the map; the Eurasian languages are all spoken in the urban centers.

- Indigenous Amerindian languages: In the Cariban family, there are Kari'na (Carib) (E: 2500; S: ca. 1200) Trio (2000); Wayana (300); Akurio (E: 50; S: 2); Tunayana (E: 80; S: fewer than 10); and Sikiïyana (E: 60; S: fewer than 10). In the Arawakan family Lokono (Arawak) (E: more than 1000; S: ca. 700) and Mawayana (Mapidian) (E: 80; S: 3) are spoken.
- English-based creole languages: Sranantongo (Sranan) is spoken as a lingua franca. In the Eastern Maroon language group (listed here in order of their relatedness to Sranantongo), Ndyuka (Aukan) (ca. 20 000), Aluku (a dialect of Aukan; ca. 2000), Paramaccan (another dialect of Aukan; ca. 3000), and Kwinti (ca. 300) are spoken. Among the Western Maroon languages, Saramaccan (ca. 25 000) and Matawai (a dialect of Saramaccan; ca. 1500) are spoken. Both include a high count of lexical items from Portuguese.
- Eurasian (European and Asian) languages: Among European languages, Dutch is spoken, along with a local variety called Surinamese Dutch. Asian languages spoken are Sarnami (Surinamese Hindi) (a koiné based on Bhojpuri, Magahi, and Avadhi) (E: ca. 130 000); Surinamese Javanese (Javanese) (E: 60 000); and Kejia (Hakka Chinese) (spoken by Hakka Chinese immigrants) (E: ca. 10 000; S: ca. 5000).

In addition to the 19 languages and dialects listed above, there is a small community of Lebanese who use Arabic, generally only in a religious context; practically all younger Lebanese are mother-tongue speakers of Dutch and Sranantongo, thus this community is subsumed under the larger Dutch/Sranantongo-speaking groups. Further, some more recent immigrant language communities have been present in Suriname for less than two or three decades, namely Portuguese-speaking Brazilians (mostly gold miners); Guyanese, who speak Creolese and/or English (Guyanese Creole English); Haitians, who speak Haitian Creole French; and an increasingly large group of newly arriving Chinese immigrants,

Romance languages, novel allomorphies seem to be correlated with stem slots. The same slots seem to be also used in etymological suppletion, and both types of suppletion appear to involve a high degree of solidarity between the inflectional forms based on the same slot.

Suriname: Language Situation

E B Carlin, Leiden University, Leiden, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Suriname (population about 440 000) is a country with enormous wealth, in terms of both natural resources and languages. The official language of the state is Dutch, which is a reflection of the fact that from 1667 until 1975 Suriname was a Dutch colony; and also of the fact that roughly 300 000 people of Surinamese descent live in the Netherlands (and thus are predominantly Dutch-speaking). Traffic between the two states by the Surinamese is constant and regular. In total, Suriname is home to 19 languages spoken by communities of different sizes who see themselves as a political, ethnic, or cultural unit, and who have Surinamese nationality and most of whom have representation of some kind in the political and economic sphere. These languages fall into three main categories: (1) indigenous Amerindian languages (Figure 1); (2) English-based creole languages; and (3) Eurasian languages that were imported from Europe and Asia. The following overview gives each of the languages followed by two numbers in parenthesis: first the size of the ethnic group (E), then the number of speakers (S); where these coincide, only one number is given. The location of the rural groups is given on the map; the Eurasian languages are all spoken in the urban centers.

- Indigenous Amerindian languages: In the Cariban family, there are Kari'na (Carib) (E: 2500; S: ca. 1200) Trio (2000); Wayana (300); Akurio (E: 50; S: 2); Tunayana (E: 80; S: fewer than 10); and Sikiïyana (E: 60; S: fewer than 10). In the Arawakan family Lokono (Arawak) (E: more than 1000; S: ca. 700) and Mawayana (Mapidian) (E: 80; S: 3) are spoken.
- English-based creole languages: Sranantongo (Sranan) is spoken as a lingua franca. In the Eastern Maroon language group (listed here in order of their relatedness to Sranantongo), Ndyuka (Aukan) (ca. 20 000), Aluku (a dialect of Aukan; ca. 2000), Paramaccan (another dialect of Aukan; ca. 3000), and Kwinti (ca. 300) are spoken. Among the Western Maroon languages, Saramaccan (ca. 25 000) and Matawai (a dialect of Saramaccan; ca. 1500) are spoken. Both include a high count of lexical items from Portuguese.
- Eurasian (European and Asian) languages: Among European languages, Dutch is spoken, along with a local variety called Surinamese Dutch. Asian languages spoken are Sarnami (Surinamese Hindi) (a koiné based on Bhojpuri, Magahi, and Avadhi) (E: ca. 130 000); Surinamese Javanese (Javanese) (E: 60 000); and Kejia (Hakka Chinese) (spoken by Hakka Chinese immigrants) (E: ca. 10 000; S: ca. 5000).

In addition to the 19 languages and dialects listed above, there is a small community of Lebanese who use Arabic, generally only in a religious context; practically all younger Lebanese are mother-tongue speakers of Dutch and Sranantongo, thus this community is subsumed under the larger Dutch/Sranantongo-speaking groups. Further, some more recent immigrant language communities have been present in Suriname for less than two or three decades, namely Portuguese-speaking Brazilians (mostly gold miners); Guyanese, who speak Creolese and/or English (Guyanese Creole English); Haitians, who speak Haitian Creole French; and an increasingly large group of newly arriving Chinese immigrants,

Figure 1 Map showing the approximate location of the Amerindian languages of Suriname. LEGEND: 1, Kari'na (Carib); 2, Wayana; 3, Trio; 4, Akuriyo; 5, Tunayana; 6, Sikiiyana; 7, Lokono (Arawak).

who speak Cantonese (Yue Chinese) and Mandarin Chinese; linguistically, socially, and economically these latter should be distinguished from the descendants of the Chinese indentured laborers who began arriving in Suriname from 1853 onwards (Tjon Sie Fat, 2002).

Language Use

Dutch, the sole official language, is used in politics, education, and in the media. Politicians may use Sranantongo and/or one of the Asian-based languages to create empathy between themselves and the people they represent. Dutch, as the prestige language, is used for written and audiovisual media, although mainstream television does devote a few hours of broadcasting a week to programs in Sranantongo; in addition, the East Indian population (called Hindustani in Suriname), who are economically more secure than most other groups, have acquired television stations in recent years and broadcast films and programs in Hindi (and/or Urdu), and to a lesser extent, current affairs

programs in Sarnami (which literally means 'Suriname (language)'). There is one Javanese television station that broadcasts mainly Indonesian soap operas, and several radio programs with political aims are broadcast in (Surinamese) Javanese. There is one Chinese daily newspaper published in modern literary Chinese. One radio station, based in Galibi, broadcasts in Kari'na, and there are two Maroon radio stations in use that broadcast in Saramaccan and Ndyuka. Much of Surinamese television now broadcasts films from North America without synchronization or subtitling, a fact that has contributed to an increase in the knowledge of English among the urban population.

The medium of education is Dutch, and given that there is compulsory primary-level education, the literacy rate in Suriname is around 90%. While ethnic languages are typically spoken at home in the urban centers, the language of the playground is Sranantongo. The main foreign languages taught at secondary school are English and Spanish. Since joining the Caribbean Community (CARICOM) in 1995, which is an English-speaking body, successive Surinamese governments have made it a priority to strengthen the teaching of English in schools.

Three main languages are used in the literary sphere in Suriname: Dutch (often interspersed with Surinamese Dutch elements), Sranantongo, and Sarnami. Most novels are written in Dutch, much poetry is written in Sranantongo and Sarnami, and a few volumes of poetry have been written in Surinamese Javanese. All other literary expression in Suriname is found in the oral traditions of all the ethnic groups. For a complete history of literature in Suriname, both oral and written, see van Kempen (2003).

Apart from the official status of Dutch, Suriname can be characterized as a country without an active language policy. The (unofficial) national language, that is, the lingua franca of Suriname, is the English-based creole language Sranantongo (literally, 'Suriname language') and is spoken with differing degrees of fluency by the majority of the population. Sranantongo is spoken as a mother tongue by many urban creoles and by many rural Amerindian communities in the northern part of the country; those Amerindian and Maroon inhabitants of the interior who have more sustained contact with the urban centers speak some Sranantongo, whereas the majority of these communities do not. The most conservative Sranantongo, which has significantly fewer loanwords from Dutch, is spoken in the districts of Coronie and Para. The level of bilingualism between Dutch and Sranantongo is high in the urban centers, and there is vibrant code-switching between the two languages. Likewise there is wide-scale code-switching between Sarnami, Dutch, and Sranantongo, between Surinamese Javanese and Sranantongo, and to a lesser extent between (Surinamese) Kejia, Sranantongo, and Dutch. The Maroon and Amerindians of the interior, because of their more isolated locations, are more often monolingual, or bilingual only in languages from the same language family, so that code-switching is not a relevant category there.

In general, in Suriname within one's own ethnic group in an informal setting, one uses the vernacular language if the participants in an event are monolingual, or Sranantongo and/or Dutch, or a code-switched version of these. In practically all formal situations, such as the workplace, administration, banks, and post offices, Dutch is the preferred language. If a speaker chooses to address someone in a formal situation in Sranantongo, then he or she is signaling that he or she perceives the listener as being uneducated. Thus, in the urban centers, given the high prevalence of bilingualism or multilingualism – albeit in different languages, depending on the ethnic background of the interlocutors – the choice of language one uses to address an interlocutor is an indicator of the speaker's real or perceived own social status as well as that of his or her interlocutor. An overview of language use and more detailed descriptions of the languages in Suriname can be found in Carlin (2001), Carlin and Arends (2002), and Charry *et al.* (1983).

Suzuki Akira (1764–1837)

N Harada, Advanced Telecommunications Research, Kyoto, Japan

© 2006 Elsevier Ltd. All rights reserved.

Akira Suzuki was born in Nagoya, Japan, in the late Edo period (1603–1868). His father was a soldier serving the Owari branch of the Tokugawa Shogun family. He practiced medicine first, then started studying Confucian literature. He resided in a house different from the main mansion and thus had the nickname *Hanareya*, meaning 'separate house'. At the age of 29, he became an apprentice of Norinaga Motoori, one of the most influential traditional Japanese grammarians at the time. Suzuki's major publications are as follows: (1) *Hataraki kotoba kiretuduki no hu* (established circa 1803) 'A chart of the conclusive and non-conclusive forms of conjugating words,' (2) *Gengyo sisyu ron* (1824) 'A theory of four types in language,' and (3) *Gago onzyoo ko* (1816) 'Reflections on the phonology of the noble words.' In *Gago onzyoo koo*, Suzuki noted that onomatopoeia plays an important role in the etymology in Japanese.

Hataraki kotoba kiretuduki no hu was never published and was circulated as a draft. Suzuki refined his master Norinaga Motoori's work on verbal conjugation and proposed eight (in the first draft) to seven (in the third and final draft) classes for the patterns of verbal conjugation in Japanese. *Hataraki kotoba kiretuduki no hu* had long been considered as being inspired by Haruniwa Motoori's *Kotoba no yatimata* 'Eight ways of words' (1808), an extensive study of the patterns of verbal conjugation in Japanese. Later, through a close examination of different versions of *Hataraki kotoba kiretudukino hu*, Motoki Tokieda (1900–1967) proved that Suzuki's work in fact inspired Haruniwa Motoori and that Suzuki should be considered as a predecessor of Haruniwa Motoori, a son of Norinaga Motoori.

In *Gengyo sisyu ron,* Suzuki classified syntactic categories into the following four groups: (1) *Tai* (nouns), (2) *Arikata* (stative predicates), (3) *Siwaza* (nonstative/eventive predicates), and (4) *Te-ni-o-ha* (noninflecting case particles and postpositions). Suzuki essentially followed the same vein as his master Norinaga Motoori in making a distinction between *te-ni-o-ha* and the other three categories, noting the following difference between *te-ni-o-ha* and the other classes shown in **Table 1**.

Table 1 Suzuki's dichotomy of lexical items in *Gengyo sisyu ron* (1824)

te-ni-o-ha	*Others (nouns and predicates)*
have no reference	have reference/meaningful content
'voices'	words
morphologically dependent	morphologically independent; words on their own
like ''strings'' (that pierce through and gather gems)	like ''gems''
like ''hands using the 'containers (that is, non-*te-ni-o-ha* categories)' ''	like ''containers''

Akira Suzuki was born in Nagoya, Japan, in the late Edo period (1603–1868). His father was a soldier serving the Owari branch of the Tokugawa Shogun family. He practiced medicine first, then started studying Confucian literature. He resided in a house different from the main mansion and thus had the nickname *Hanareya*, meaning 'separate house'. At the age of 29, he became an apprentice of Norinaga Motoori, one of the most influential traditional Japanese grammarians at the time. Suzuki's major publications are as follows: (1) *Hataraki kotoba kiretuduki no hu* (established circa 1803) 'A chart of the conclusive and non-conclusive forms of conjugating words,' (2) *Gengyo sisyu ron* (1824) 'A theory of four types in language,' and (3) *Gago onzyoo ko* (1816) 'Reflections on the phonology of the noble words.' In *Gago onzyoo koo*, Suzuki noted that onomatopoeia plays an important role in the etymology in Japanese.

Hataraki kotoba kiretuduki no hu was never published and was circulated as a draft. Suzuki refined his master Norinaga Motoori's work on verbal conjugation and proposed eight (in the first draft) to seven (in the third and final draft) classes for the patterns of verbal conjugation in Japanese. *Hataraki kotoba kiretuduki no hu* had long been considered as being inspired by Haruniwa Motoori's *Kotoba no yatimata* 'Eight ways of words' (1808), an extensive study of the patterns of verbal conjugation in Japanese. Later, through a close examination of different versions of *Hataraki kotoba kiretudukino hu*, Motoki Tokieda (1900–1967) proved that Suzuki's work in fact inspired Haruniwa Motoori and that Suzuki should be considered as a predecessor of Haruniwa Motoori, a son of Norinaga Motoori.

In *Gengyo sisyu ron,* Suzuki classified syntactic categories into the following four groups: (1) *Tai* (nouns), (2) *Arikata* (stative predicates), (3) *Siwaza* (nonstative/eventive predicates), and (4) *Te-ni-o-ha* (noninflecting case particles and postpositions). Suzuki essentially followed the same vein as his master Norinaga Motoori in making a distinction between *te-ni-o-ha* and the other three categories, noting the following difference between *te-ni-o-ha* and the other classes shown in Table 1.

Table 1 Suzuki's dichotomy of lexical items in *Gengyo sisyu ron* (1824)

te-ni-o-ha	*Others (nouns and predicates)*
have no reference	have reference/meaningful content
'voices'	words
morphologically dependent	morphologically independent; words on their own
like ''strings'' (that pierce through and gather gems)	like ''gems''
like ''hands using the 'containers (that is, non-*te-ni-o-ha* categories)' ''	like ''containers''

Suzuki's dichotomy between *te-ni-o-ha* elements and non-*te-ni-o-ha* elements had much influence on Motoki Tokieda, who proposed a dichotomy for syntactic categories, dividing the lexicon into '*si*' (content words) and '*zi*' (functional elements). This dichotomy shares the same insight as the current syntactic theory (see Chomsky and Lasnik, 1993 for references), where the lexicon is divided up into lexical/thematic categories and functional categories.

The subdichotomy between stative and nonstative predicates proposed by Suzuki inspired a modern traditional Japanese grammarian Kenzi Ishigaki (1914–1947), who discovered a correlation between the stativity of predicates, and the alternation of the genitive case particle *no* and the nominative marker *ga* in an adnominal clause modifying a nominal head (see Ishigaki, 1942).

Swadesh, Morris (1909–1967)

M Makihara, Queens College, CUNY, Flushing, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Morris Swadesh, a highly regarded linguistic anthropologist, is perhaps best known for his creation in the 1950s of glottochronology and lexicostatistics, methods for dating the divergence of related languages. He was born in 1909 in Holyoke, Massachusetts, of Russian Jewish parents, from whom he learned Yiddish. As an undergraduate he studied German and French at the University of Chicago. His career as a linguist started as a student of Edward Sapir at Chicago and then at Yale University, where he completed his Ph.D. dissertation in 1933 on the semantics of Nootka (a Native American language spoken in Southwestern British Columbia, Canada). He also published papers on the phonology, morphology, and syntax of Nootka, and a book in collaboration with Sapir, *Nootka texts* (1939). After completing his dissertation, he remained at Yale to work on synchronic phonological theory and American English grammar until 1937, when he was appointed Assistant Professor at the University of Wisconsin–Madison.

Building on the works by Sapir and others, he made important contributions through his papers 'The phonemic principle' (1934) and 'A method for phonetic accuracy and speed' (1937), which clarified the certain aspects of phonemic analysis.

Swadesh also became interested in linguistic change, which he first explored by looking at its relation to phonetic complexity and then through comparative analyses of lexicons. Starting in 1950, he introduced a controversial statistical method to measure the degree of relatedness among language varieties, and over several years he elaborated his quantitative methodology of lexicostatistics and the glottochronological method to date ancestor languages. In his well-known paper 'Lexico-statistic dating of prehistoric ethnic contacts' (1952) he argued that a basic 'noncultural' vocabulary of items tends to resist replacement at a relatively constant retention rate of about 81% over 1000 years. He compiled a vocabulary list that came to be known as the 'Swadesh list' of 215 words, which later was revised to 200 and finally 100 words (Swadesh, 1955). While various critiques were made, for example, regarding the assumption that one can construct a set of noncultural words for all languages without being biased by Western notions of what are

Suzuki's dichotomy between *te-ni-o-ha* elements and non-*te-ni-o-ha* elements had much influence on Motoki Tokieda, who proposed a dichotomy for syntactic categories, dividing the lexicon into '*si*' (content words) and '*zi*' (functional elements). Morris Swadesh, a highly regarded linguistic anthropologist, is perhaps best known for his creation in the 1950s of glottochronology and lexicostatistics, methods for dating the divergence of related languages. He was born in 1909 in Holyoke, Massachusetts, of Russian Jewish parents, from whom he learned Yiddish. As an undergraduate he studied German and French at the University of Chicago. His career as a linguist started as a student of Edward Sapir at Chicago and then at Yale University, where he completed his Ph.D. dissertation in 1933 on the semantics of Nootka (a Native American language spoken in Southwestern British Columbia, Canada). He also published papers on the phonology, morphology, and syntax of Nootka, and a book in collaboration with Sapir, *Nootka texts* (1939). After completing his dissertation, he remained at Yale to work on synchronic phonological theory and American English grammar until 1937, when he was appointed Assistant Professor at the University of Wisconsin–Madison.

Building on the works by Sapir and others, he made important contributions through his papers 'The phonemic principle' (1934) and 'A method for phonetic accuracy and speed' (1937), which clarified the certain aspects of phonemic analysis.

Swadesh also became interested in linguistic change, which he first explored by looking at its relation to phonetic complexity and then through comparative analyses of lexicons. Starting in 1950, he introduced a controversial statistical method to measure the degree of relatedness among language varieties, and over several years he elaborated his quantitative methodology of lexicostatistics and the glottochronological method to date ancestor languages. In his well-known paper 'Lexico-statistic dating of prehistoric ethnic contacts' (1952) he argued that a basic 'noncultural' vocabulary of items tends to resist replacement at a relatively constant retention rate of about 81% over 1000 years. He compiled a vocabulary list that came to be known as the 'Swadesh list' of 215 words, which later was revised to 200 and finally 100 words (Swadesh, 1955). While various critiques were made, for example, regarding the assumption that one can construct a set of noncultural words for all languages without being biased by Western notions of what are

basic words, and whether a universally constant rate of retention can be established for changes in this list, his method served as a useful starting point for historical linguistic investigations of previously unwritten languages and generated many comparative analyses in the years to follow. He died in 1967 while working on his last major work, *The origin and diversification of language* (1971), which outlined his theory of the evolution of vocabulary imitation and sound symbolism and presented his analysis of language divergence.

During World War II he served as a linguist for the War Department in New York City, then he became Associate Professor at City College of New York in 1948. In 1949, however, City College abruptly decided not to renew his appointment. In that same year, he had been investigated by the McCarthy Committee and indicted for his past membership in the Communist party and for public statements and activities viewed as sympathetic to the party. After losing his teaching position at City College, in 1956 he moved to Mexico City, where he served as professor at the Instituto de Historia, Universidad Nacional Autónoma de México, and the Escuela Nacional de Antropología e Historia, where he continued to do research and publish. He died of a heart attack in 1967. A list of Swadesh's writings was compiled by Stanley Newman (1967).

Introduction

Swahili is a Bantu language spoken by over 50 million (first- and second-language) speakers in East Africa, including Tanzania and Kenya, where it is a national language, and parts of Somalia, Uganda, Rwanda, Burundi, the Democratic Republic of Congo, and Mozambique. In terms of classification, Swahili belongs to the Sabaki group of the Northeast Coast Bantu languages, and it is part of group G of Guthrie's (1967–1971) referential classification. Like many Bantu languages, Swahili has elaborate noun class and agreement systems, and complex verbal morphology.

Language History

Swahili has been spoken on the East African coast since approximately 800 A.D., after Bantu-speaking people from the Great Lakes region reached the coast. The earliest Swahili speakers, after the language separated from those Sabaki languages most closely related to it, probably settled in northern Kenya on the mouth of the river Tana. Due to the maritime trading of the Swahili, the language became

basic words, and whether a universally constant rate of retention can be established for changes in this list, his method served as a useful starting point for historical linguistic investigations of previously unwritten languages and generated many comparative analyses in the years to follow. He died in 1967 while working on his last major work, *The origin and diversification of language* (1971), which outlined his theory of the evolution of vocabulary imitation and sound symbolism and presented his analysis of language divergence.

During World War II he served as a linguist for the War Department in New York City, then he became Associate Professor at City College of New York in 1948. In 1949, however, City College abruptly decided not to renew his appointment. In that same year, he had been investigated by the McCarthy Committee and indicted for his past membership in the Communist party and for public statements and activities viewed as sympathetic to the party. After losing his teaching position at City College, in 1956 he moved to Mexico City, where he served as professor at the Instituto de Historia, Universidad Nacional Autónoma de México, and the Escuela Nacional de Antropología e Historia, where he continued to do research and publish. He died of a heart attack in 1967. A list of Swadesh's writings was compiled by Stanley Newman (1967).

Introduction

Swahili is a Bantu language spoken by over 50 million (first- and second-language) speakers in East Africa, including Tanzania and Kenya, where it is a national language, and parts of Somalia, Uganda, Rwanda, Burundi, the Democratic Republic of Congo, and Mozambique. In terms of classification, Swahili belongs to the Sabaki group of the Northeast Coast Bantu languages, and it is part of group G of Guthrie's (1967–1971) referential classification. Like many Bantu languages, Swahili has elaborate noun class and agreement systems, and complex verbal morphology.

Language History

Swahili has been spoken on the East African coast since approximately 800 A.D., after Bantu-speaking people from the Great Lakes region reached the coast. The earliest Swahili speakers, after the language separated from those Sabaki languages most closely related to it, probably settled in northern Kenya on the mouth of the river Tana. Due to the maritime trading of the Swahili, the language became

established in Swahili settlements along the coast from Mogadishu in the north to Cap Delgado in the south. Still today, the majority of first-language speakers of Swahili live on the East African coast of Tanzania and Kenya and the adjacent islands. Through continuous contact with Arab traders, many Swahili became Muslims, and a large number of loanwords from Arabic have entered the language over the centuries, leading sometimes to the mistaken believe that Swahili is a mixed language. The Swahili coastal city-states became important centers of the Indian Ocean trade, and in the wake of increasing political and economic power, Swahili poetry flourished, in particular in the Lamu (Kiamu), Pate (Kipate), and Mombasa (Kimvita) dialects, with the earliest surviving Swahili manuscripts, written in Arabic script, dating to the first half of the 18th century. In the 19th century, Zanzibar became part of, and indeed the capital of, the Sultanate of Oman, and the Zanzibar Swahili dialect Kiunguja became more prestigious. During this period, Swahili traders established trade routes into the area beyond the coast, and the language spread with it. During the colonial period, Swahili was used as a language of administration, especially by the German colonialists in Tanganyika, but it was also a language of interethnic communication in the anticolonial struggle. After independence, Swahili became the national language of Tanzania and Kenya, in both countries sharing the status as official language with English. In Tanzania, and to a lesser extent in Kenya, Swahili is widely used in public administration, education (especially primary education), and the media. Especially in the urban centers, Swahili is increasingly the first language of younger Tanzanians and Kenyans. Swahili is also used to varying degrees in Somalia, Uganda, Rwanda, Burundi, Democratic Republic of Congo, and Mozambique. Outside of East Africa, there are Swahili-speaking communities in the Gulf states and in many Western countries, including the UK (often East-African Indians), and Swahili is taught as a foreign language in language schools and universities throughout the world.

Standard Swahili

There are a number of Swahili dialects spoken today, including the dialects of the Lamu archipelago (Kiamu, Kisiu, Kipate) and Kimvita, associated with classical Swahili literature, and Kiunguja, the dialect of Zanzibar town. Chimwiini and Bajuni, the traditional Swahili dialects of the Somali coast, are currently highly endangered due to the displacement of the Swahili-speaking communities in Somalia, and there are today probably more speakers in Kenya. Comparatively little is known about the more southern Swahili dialects such as Kingome spoken on Mafia island. A distinct variety of Swahili is also spoken in Lubumbashi and the Shaba province in the Democratic Republic of Congo. More recently, distinct urban varieties of Swahili are emerging, for example, the mixed code Sheng of Nairobi. The most important variety of Swahili today is the so-called Standard Swahili (*Kiswahili sanifu*). Since the beginning of the 19th century, various bodies, political and missionary, have made proposals for the development of a standard variety of Swahili. Missionaries began to write Swahili in Roman script, and in 1930 the British-run Inter-territorial Language Committee established the standard form of Swahili based on Kiunguja, which is used today. After independence, strong efforts were made by East African governments to develop Swahili further through research as well as through vocabulary development and standardization, e.g., through the *Baraza la Kiswahili la Taifa* (National Swahili Council) and the *Taasisi ya Uchunguzi wa Kiswahili* (Institute for Swahili Research) in Tanzania. While the development and status of Swahili is often, and rightly, cited as a successful example for the use of an African language as a modern national and official language in postcolonial Africa, it is also leading to an increasing endangerment of Swahili dialects and many of the about 200 languages spoken in Kenya and Tanzania, a problem which has been addressed only recently.

Structure

Swahili exhibits typical Bantu structural characteristics such as an articulated noun class system and morphologically marked agreement between different constituents of clauses and sentences. The morphology is complex and Swahili is often classified as an agglutinating language. Word order, especially within the sentence, is syntactically comparatively free and often motivated by information structure. A remarkable difference from most other Bantu languages is the absence of tone in Swahili.

Noun Classes

A noun class system can be thought of as being halfway between a grammatical gender system as in German or French, and classifier systems as found, for example, in Thai or Chinese. In Swahili, every noun is assigned to a specific noun class, and noun classes are in general marked by a class prefix. Thus, for example, the word *mtoto* 'child' consists morphologically of the noun class prefix *m-* and the stem *-toto*. Noun classes often express number

Table 1 Swahili noun classes and agreement

Class	*Noun class prefix*[a]	*Example word*	*Concord*[b]	*Relative concord*	*Possessive concord*	*Dem prox*	*Dem ref*	*Dem non-prox*
1	m	mtu 'person'	a/yu	ye	wa	huyu	huyo	yule
2	wa	watu 'people'	wa	o	wa	hawa	hao	wale
3	m	mti 'tree'	u	o	wa	huu	huo	ule
4	mi	miti 'trees'	i	yo	ya	hii	hiyo	ile
5	ji	jicho 'eye'	li	lo	la	hili	hilo	lile
6	ma	macho 'eyes'	ya	yo	ya	haya	hayo	yale
7	ki	kiti 'chair'	ki	cho	cha	hiki	hicho	kile
8	vi	viti 'chairs'	vi	vyo	vya	hivi	hivyo	vile
9	n	ndege 'bird'	i	yo	ya	hii	hiyo	ile
10	n	ndege 'birds'	zi	zo	za	hizi	hizo	zile
11	u	ubao 'board'	u	o	wa	huu	huo	ule
14	u	uhuru 'freedom'	u	o	wa	huu	huo	ule
15	ku	kuimba 'to sing'	ku	ko	kwa	huku	huko	kule
16[c]	pa		pa	po	pa	hapa	hapo	pale
17[c]	ku		ku	ko	kwa	huku	huko	kule
18[c]	mu		mu	mo	mwa	humu	humo	mule

[a]Noun class prefix is also used for adjective agreement.
[b]Concord is used as SM, OM (except in class 1, where SM = *a-*, OM = *m(w)-*).
[c]There are no words in classes 16–18; these are only used in agreement.

distinction, so that *watoto*, with a different noun class prefix *wa-*, means 'children.' It is customary in Bantu linguistics to group noun classes according to a numerical system first proposed by Bleek (1869) (see Table 1).

Swahili has 16 different noun classes, which have a more or less transparent semantic base. Nouns in classes 1 and 2 denote only humans (but not all humans are in class 1/2), class 14 is used to refer to abstract qualities, class 15 has verbal infinitives, and classes 16–18 are locative classes. For the remaining classes, the semantic base is less obvious. For example, class 3/4 contains a number of words denoting plants and trees, class 9/10 contains names of animals, and class 6 contains liquids. However, in all of these, there are many words that do not fit a semantic characterization. Another use of the noun classes is for nominal derivation, by shifting nouns from one class to the other. For example, shifting nouns into class 7/8 denotes diminutive: *kitoto* 'a small child,' while class 6 can be used to express a group of individuals, rather than just plurality: *fisi* (class 10), 'hyenas,' *mafisi* (class 6) 'a pack of hyenas.'

Agreement

The noun classes are important for the agreement system of Swahili, as adjectives, demonstratives, and relative clauses show their syntactic relationship with their nominal head through agreement affixes, or concords. Similarly, verbal agreement morphology marks subjects and objects of the verb. For example, in (1), the demonstrative pronoun and the adjective show their syntactic relation to the head noun *vitabu* (of class 8) by the concord morpheme *vi-*.

(1) vi-tabu vi-le vi-zuri
books *those* *beautiful*
'those beautiful books'

The shape of agreement affixes is not always identical with the noun class prefix. While the agreement morpheme is identical to the noun class prefix in the case of adjective agreement, with demonstratives, it may have a different shape, as for example with a class 6 head noun, where the noun class prefix is *ma-*, but the agreement morpheme of the demonstrative is *ya-* (see Table 1 for an overview of these forms in all classes):

(2) ma-chungwa ya-le ma-zuri
oranges *those* *beautiful*
'those beautiful oranges'

Verbs show agreement with subjects and objects, by means of subject (SM) and object markers (OM), as in (3):

(3) m-toto a-li-wa-angali-a wa-zazi w-ake
child SM1-PAST-OM2-*look_at*-FIN NP2-*parents* CD2-*his/her*
'the child looked at his/her parents'

The term 'agreement' in relation to verbs can be misleading, as no overt noun phrases are needed for a grammatical sentence; in (4) the subject and object

marker function more like pronouns in languages like English:

(4) a-li-wa-angali-a
SM1-PAST-OM2-*look_at*-FIN
's/he looked at them'

The subject marker is an obligatory part of the inflected verbs in most tenses, while the object marker is (near) obligatory with human objects, but is used according to semantic and pragmatic considerations (for example, to indicate a specific object or discourse topic) with all other classes.

A number of aspects of the Swahili agreement system pose interesting problems from a theoretical perspective, for example the resolution of agreement with conjoined NPs, or the exact characterization of the status of object agreement. Furthermore, the relation of the Swahili agreement system to the systems of other Bantu (and indeed non-Bantu) languages provides a good testing ground for comparative and historical studies.

Verbal Morphology

Inflected Swahili verbs are, as already seen above, morphologically comparatively complex. In a morphological template for Swahili verbs, ten positions can be identified. Not all of these positions can be filled at the same time, but normally, at least positions 2, 4, 8, and 9 are filled (as in example [5]). Six and seven positions are filled in (6) and (7):

1	2	3	4	5	6
Pre Initial Neg	SM	Post Initial Neg	Tense Marker	Relative Marker	Stem marker
	7 OM	8 Verbal Base	9 Final	10 Post Final Plural	

(5) wa-ta-som-a
SM2-FUT-*read*-FIN
'they will read'

(6) wa-na-o-ku-j-a
SM2-PRES-REL2-STEM-*come*-FIN
'they who come'

(7) ha-wa-ta-ku-ambi-e-ni
NEG-SM2-FUT-OM2-*tell*-FIN-PL
'they will not tell you (pl.)'

In addition to inflectional morphology, verbs can be modified by a number of derivational suffixes, or extensions, suffixed to the verbal root before the final. For example, the causative of *soma* 'read' is *somesha* 'cause to read, teach.' Verbal extensions change the meaning of the base verb and in many cases interact in complex ways with the valency of the base. Among the most productive extensions in Swahili are passive (*-w-*), causative (*-ish-*, *-esh-*), applicative (*-i-*, *-e-*), neutro-passive (*-ik-*, *-ek-*), separative (*-u-*, *-o-*), reciprocal (*-an-*), and stative-positional (*-am-*). The surface forms of these morphemes is determined by phonological processes such as vowel harmony. For example, *funga* 'tie, open,' *fungua* 'untie, close,' *fungia* 'tie for/with someone/something,' *fungika* 'be closable,' *fungana* 'fasten together,' *fungwa* 'be closed,' *funguliwa* 'be opened' (separative and passive), and *fungiana* 'tie for each other' (applicative and reciprocal). The last two examples show that more than one extension can be used. The exact meaning and function of extended verbs depends very much on the meaning of the base verb and on the (syntactic and nonsyntactic) context in which they are used.

Syntax

The basic word order of Swahili in the phrase is head-modifier, and SVOA in the sentence (8). However, word order can be changed to adapt to the specific discourse-pragmatic situation. Often focused elements are placed at the right periphery of the sentence or phrase, and topicalized elements at the left periphery (9, 10, adapted from Ashton, 1947: 301):

(8) Asha a-li-m-kut-a Juma njia-ni.
Asha SM1-PAST-OM1-*meet*-FIN *Juma* 9.*street*-LOC
'Asha met Juma in the street'

(9) ndoo hizi zi-jaz-e ma-ji
10.*buckets* *these* OM10-*fill*-SUBJ NP6-*water*
'these buckets, fill them with water'

(10) zi-jaz-e ma-ji ndoo
OM10-*fill*-SUBJ NP6-*water* 10.*buckets*
'fill the buckets (not tin cans) with water'

Within the noun phrase, a common strategy to change word order is so-called possessor raising, where in a genitive construction the possessor, which normally follows the possessed, is fronted. In (11), within the subject NP, *mtoto yule* is possessor-raised (cf. *mambo ya(ke) mtoto yule yamenichosha*). In (12), *Sudi* is possessor-raised (cf. *wale wanaojua tabia ya(ke) Sudi*):

(11) m-toto yule ma-mbo yake
NP1-*child* *this* NP6-*affairs* *his*
ya-me-ni-chosh-a
SM6-PERF-OM1sg-*make_tired*-FIN
'as for this child, his affairs make me tired'

(12) . . . hasa wale
. . . *especially* *those*
wa-na-o-m-ju-a Sudi tabia yake
SM2-PRES-REL2-OM1-*know*-FIN *Sudi character his*
'. . . especially those who know Sudi's character'
(Kibao, 1975: 50)

Note that in (12), the object marker agrees with *Sudi*, which is not actually the structural object of *-jua*. Similarly, Maw (1970) reports that in sentences such as (11), 'subject' agreement both with subject, as in (11), but also with the possessor-raised topic are possible (i.e., *amenichosha*). As mentioned above, further work is needed on the analysis of agreement.

Another area of interaction between word order, syntactic function, and agreement are so-called locative inversion structures. In (13), the locative is fronted and the logical subject follows the verb (cf. *watu wengi wamelala humu nyumbani*). Note that the subject marker agrees with the locative phrase, making it the grammatical subject. In (14), the subject marker 'agrees' with an unexpressed locative, and the subject follows the verb (cf. *hotuba mbali mbali zikatolewa*):

(13) humu nyumba-ni m-me-lal-a
in_here *house*-LOC SM18-PERF-*sleep*-FIN
watu wengi
people *many*
'many people are asleep in this house'
(Ashton, 1947: 300)

(14) pa-ka-tol-ew-a hotuba mbali mbali
SM16-CONSEC-*take_out*-PASS-FIN *speeches* *different*
'and there were held different speeches'
(Kibao, 1975: 50)

Like with many Bantu languages, the formal study of Swahili syntax is only at its beginning, and many constructions, including some of the ones mentioned here, await further analysis.

Swales, John (b. 1938)

M Newman, Queens College/City University of New York, Flushing, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

John Swales is one of the inventors of the field of literacy studies and a prominent researcher in this area. His focus is on English for academic purposes, particularly for advanced graduate students, a group he had worked with for many years at the University of Michigan as director of the English Language Institute. He is currently a professor of linguistics there.

Swales was born in 1938 in South London and received his B.A. and M.A. in psychology from Cambridge in 1964. He then 'drifted into' applied linguistics through English as a foreign language (EFL), a profession he picked "as a way of seeing the world, as much as anything." Swales began to see the world in the 1960s, first in Italy, then Sweden, and finally Libya, where he became head of the University of Libya English Department. He moved back to England in 1970 to teach at the University of Leeds but returned to Africa 3 years later, this time as director of English Language Services at the University of Khartoum in Sudan. He stayed in that position for 5 years, after which he returned to England as a senior lecturer at the University of Aston. In 1985, he moved abroad again, this time to the University of Michigan.

Unusual for an academic, Swales does not hold a Ph.D., but he has more than made up for that lacking through 15 single and coauthored books. These range from textbooks (Swales and Feak, 2004) to theoretical works (Swales, 1990), ethnographies of communication (Swales, 1998), and, of all things, a field guide for birds (Kielb *et al*., 1993).

Like all good EFL teachers, Swales was also a learner of the cultures of his students and the interaction between those cultures and language learning. To understand the challenges involved, he developed the concept of 'discourse community,' a group that uses specific communication patterns to achieve common goals. A central feature of all discourse communities is their use of specific genres; in fact, the normative use of common genres and common generic norms helps define a discourse community. Academics, or perhaps specific disciplines, are obvious cases, and one goal of students, particularly graduate students, is to enter such a community. However, the concept is not limited to academics; Swales's most famous example is the Hong Kong Study Circle, a philatelic group he belonged to specializing in Hong Kong stamps.

Current literacy theory is rooted in the insight that it is possible to determine what makes first written communication successful by examining it with a sociolinguistic sensibility (i.e., uncovering associations between textual forms and social purposes). This approach is often traced to Michael Halliday's (1977) sociosemiotic linguistics. However, Swales's notion of discourse community emphasizes generic norms, and thus recalls Labov's (1973) formulation of 'speech community.' The resulting emphasis on social processes over formal features has allowed useful tie-ins to influential educational, although not specifically linguistic, concepts such as 'communities of practice' (Lave and Wenger, 1991).

Swaziland: Language Situation

N L Thwala, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

English and SiSwati are the official languages of Swaziland. The majority of the population speaks SiSwati as a first language whereas English is learned as a second language in Schools. Both languages are taught in Schools and are used in the media (radio, television broadcasting and print media). The two languages differ in status, however. English enjoys dominant status as the language of written and oral communication in the corporate business environment, education sector, the judiciary and media. The dominant status of English is so complete in the education sector that all subjects (except SiSwati itself) are taught in English. And passing English is a requirement for admission to university. In print media, there are two daily newspapers in English and only one weekly newspaper in SiSwati. Television broadcasts are all in English except for one daily news broadcast in SiSwati and the occasional culture program. There is also an English radio service whose programs target the youth, especially the urban youth.

SiSwati is a language spoken by people who call themselves EmaSwati, who are found principally in the Kingdom of Swaziland and in the Republic of South Africa. Nationals of Swaziland refer to their country as KaNgwane, which means 'the place of Ngwane' (Ngwane is the name of one of their legendary kings). The language is called SiSwati by its speakers, but it is also referred to as IsiSwazi.

The exact number of speakers of SiSwati is not known, since no scientific survey has ever been undertaken to determine this. It is estimated that there are 1 million speakers in the Kingdom of Swaziland and 1.6 million speakers in the Republic of South Africa.

SiSwati is largely an oral language, with written SiSwati less common. Radio is by far the most pervasive medium of mass communication: one in South Africa (Lingwalagwala FM) and one in Swaziland (Swaziland Broadcasting Service). Both radio broadcasts have overlapping coverage, but of the two, the South African radio station reaches all parts of Swaziland, whereas the Swaziland radio station only reaches some parts of South Africa. According to the South African Broadcasting Service (SABC) media sales report, Lingwalagwala reaches an audience of about 1.5 million listeners per week. In television broadcasts, SiSwati use is restricted to news broadcasts and the occasional culture program. In Swaziland there is a daily news broadcast in SiSwati the evening.

Despite being largely an oral language, SiSwati is not used in all discourse contexts. It is officially not a language of instruction or examination at all levels of education, except in the instruction or examination of SiSwati itself. SiSwati is thus not a language of academic discourse. It is also not a language of corporate business discourse, where the tendency is to speak English.

Writing in SiSwati is mostly restricted to official publications from government departments and nongovernmental organizations, as well as mass communication literature. For example, literature on public health and community development is available in SiSwati published by government departments and nongovernmental organizations. Another large source of SiSwati publications is the education sector in the form of school textbooks and school readers for the teaching of SiSwati language and literature.

As can be expected, there are various dialects of SiSwati, which have arisen partly as a result of language contact. Within Swaziland, there are two main dialects: the Shiselweni dialect and the standard dialect. The Shiselweni dialect is influenced by IsiZulu, since it is in the region that borders the Zulu-speaking area (KwaZulu-Natal Province in the Republic of South Africa). The most salient properties of the Shiselweni dialect are phonological. For example, where the standard dialect exhibits affricates, the Shiselweni dialect will reflect stops, as in the following contrasts.

(1)	umuntfu	umundu	'human being'
(2)	Sidzakwa	sidakwa	'drunkard'
(3)	indvodza	indodza	'man'
(4)	sitfunti	sithunti	'shadow'

There are other dialects, but they have received less attention. For example, a distinct dialect exists along the Swaziland–Mozambique border that is influenced by XiTsonga, a language spoken in Mozambique.

Sweden: Language Situation

A Lindskog, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Sweden has a population of about 9 million, for 90% of whom Swedish is the mother tongue. Swedish, though not *de jura* the official language, is used dominantly in administration, education, media, and public life. There are a number of minority languages, both historical and new immigrant languages, and five of the former (Finnish, Sami, Meänkieli, Yiddish, Romani) received official minority language status in April, 2000. This minority status gives the speakers of the first three the right to use them when dealing with authorities in designated areas, as well as being able to insist on preschool and elderly care in these languages. It also encourages government to undertake work specifically to improve conditions for the five official national minorities and to help safeguard and develop their languages, and teaching of these minorities and their languages is stipulated in the national curriculum.

The five selected languages have all existed in Sweden for centuries, in the cases of Finnish and Sami for as long as Swedish. Today there are about 450 000 first-generation and second-generation Finns in Sweden, but there are no exact figures on how many of them have Finnish as their mother tongue, as comprehensive data on ethnicity and language preference have not yet been collected in Sweden (all subsequent figures are estimates).

The Sami number around 15 000 in the Swedish part of Sápmi (an area covering mainly the western side of the northern half of Sweden), and it is thought that at least half can speak Sami. South Sami, North Sami, and Lule Sami are the dominant varieties – Pite Sami and Ume Sami are also still spoken, but with only a handful of speakers, each is threatened with extinction. All of these varieties are covered by the Minority Language Act. There are provisions in some regions for Sami children to receive tuition in Sami language, culture, and heritage (in both designated Sami schools and regular schools). The Sami Parliament works pro-actively to promote Sami, and Umeå University teaches courses in Sami both at beginners' level and for native speakers.

Meänkieli, or Tornedalen Finnish, is spoken mainly in the north of Sweden in the area bordering Finland. It has derived from standard Finnish, with heavy influence from Swedish, and is spoken by between 40 000 and 70 000 people. A certain revival of interest in the language has taken place over the last 20 years, and there are now several books published in Meänkieli. Pajala municipality, alongside various interest groups, works to promote the use and learning of Meänkieli, and it is taught at some institutions of higher education.

There are about 17 000 to 25 000 Jews in Sweden and about 4000 of them are thought to have a thorough knowledge of Yiddish. Many more can understand but not speak it, and many have no comprehensive knowledge but use certain words and expressions daily.

Romanys are known to have lived in Sweden since at least the 16th century. Their language is mostly a spoken vernacular, and many varieties, or dialects, exist. It is estimated that there are about 15 000 to 20 000 Romanys in Sweden, and the minority language status incorporates all varieties of Romani.

Along with the historical minority languages, many newer immigrant languages are spoken, bringing the total of languages in Sweden to nearly 200. After Finnish, the largest groups include Norwegian, Danish, and languages of the former Yugoslavia. All students in primary or secondary education with a mother tongue or 'home-language' other than Swedish have the right to receive 'home-language tuition' (*hemspråksundervisning*), following a law passed in 1977.

Knowledge of English is relatively high, and many people speak a second foreign language in addition. English is taught from the age of 6 or 7. Pupils are encouraged to take up German, French, or Spanish in secondary school.

With English becoming increasingly influential, and an unprecedented influx of immigrants, a parliamentary report into the current state and future development of language in Sweden was undertaken in 2002 (*Mål i mun*). In April, 2002, the report recommended that the position of Swedish be strengthened, that everyone's right to (their own) language be safeguarded, and that learning of other languages be promoted. Work on a language law, which is expected to follow the report's recommendations, is currently underway.

Swedish

K Börjars, The University of Manchester, Manchester, UK

© 2006 Elsevier Ltd. All rights reserved.

Swedish is spoken natively by ~8.5–9 million people in Sweden and by ~250 000–300 000 people in Finland. It is a Germanic language, part of the North Germanic branch, along with Norwegian, Danish, Icelandic, and Faroese. There is a fair degree of mutual intelligibility between Swedish and the other so-called mainland Scandinavian languages. The early historical stages of the North Germanic languages are normally divided into an eastern group (the dialects of the present Norway, Iceland, and Faroe Islands) and a western group (the dialects of Sweden and Denmark), As the language situation developed and Danish and Swedish crystallized as two separate languages, a north–south division became increasingly appropriate. The year 1526 is normally taken as the beginning of Modern Swedish, at which time Sweden won independence from Denmark and the first Swedish translation of the New Testament began to be circulated.

The language was originally written in runes carved in stone, but early Christian missionaries brought the idea of writing on parchment and with it the Latin alphabet. There are books preserved from as early as the beginning of the 13th century. The modern Swedish alphabet contains 28 letters; the same as those of the English alphabet, except that there is no 'w' and there are three additional letters at the end of the alphabet (å, ä, and ö). Swedish underwent a spelling reform in 1906 and its spelling is now quite regular, though there are a few sounds that can be represented in a number of different ways, most notoriously /ʃ/, which can be spelled *sk*, *sj*, *stj*, *skj*, *ch*, and *sch*, and /j/, which can be spelled *j*, *gj*, *hj*, *dj*, and *lj*.

Phonologically, Swedish is characterized by a relatively large number of vowels. The 18 vowels are frequently grouped into nine pairs; the main difference within each pair is length, but there are also associated differences in quality. Standard Swedish does not have phonemic diphthongs, though the pronunciation of long vowels may involve some diphthongization. The consonants are also realized as long or short, with little or no difference in quality. Long sounds may only occur in stressed syllables and every stressed syllable must contain either a long vowel or a long (or double) consonant. When any of the consonants /t d s n l/ immediately precede /r/, the two consonants are then realized as a retroflex, /ʈ ɖ ʂ ɳ ɭ/, respectively.

Swedish, apart from the Swedish spoken in Finland, makes a distinction that is often referred to as tonal, i.e., there is a difference between Accent I (or *akut accent*) and Accent II (or *grav accent*). The distinction is one of word accent. The difference between the two accents is mainly one of pitch, but Accent II, which is limited to bi- and polysyllabic words, has an effect of some secondary stress on the syllable immediately following the syllable with main stress. There are a number of minimal pairs in the language, distinguished only by Accent I versus Accent II, as in Examples (1a) and (1b), where I or II indicates the type of accent (abbreviation: DEF, definite):

(1a) ˈtomten — ˈˈtomten
yard.DEF — gnome/father Christmas.DEF

(1b) ˈanden — ˈˈanden
duck.DEF — spirit.DEF

Swedish verb morphology is relatively simple, with no agreement marking in any tense. The present–past distinction is made morphologically, whereas perfect aspect is marked by the auxiliary *ha* 'have,' followed by a form of the verb referred to as the 'supine.' For passive, there is both a morphological and a syntactic version, and a number of subtle factors influence the choice between the two. A paradigm for the verb *kittla* 'tickle.INFINITIVE' is provided in Example (2) (SG, singular; PL, plural; PRES, present; PERF, perfect; S PASS, BLI PASS, morphological and syntactic passive; FEM, feminine):

Standard Swedish does not have phonemic diphthongs, though the pronunciation of long vowels may involve some diphthongization. The consonants are also realized as long or short, with little or no difference in quality. Long sounds may only occur in stressed syllables and every stressed syllable must contain either a long vowel or a long (or double) consonant. When any of the consonants /t d s n l/ immediately precede /r/, the two consonants are then realized as a retroflex, /ʈ ɖ ʂ ɳ ɭ/, respectively.

Swedish, apart from the Swedish spoken in Finland, makes a distinction that is often referred to as tonal, i.e., there is a difference between Accent I (or *akut accent*) and Accent II (or *grav accent*). The distinction is one of word accent. The difference between the two accents is mainly one of pitch, but Accent II, which is limited to bi- and polysyllabic words, has an effect of some secondary stress on the syllable immediately following the syllable with main stress. There are a number of minimal pairs in the language, distinguished only by Accent I versus Accent II, as in Examples (1a) and (1b), where I or II indicates the type of accent (abbreviation: DEF, definite):

(1a) ˈtomten — ˈˈtomten
yard.DEF — gnome/father Christmas.DEF

(1b) ˈanden — ˈˈanden
duck.DEF — spirit.DEF

Swedish verb morphology is relatively simple, with no agreement marking in any tense. The present–past distinction is made morphologically, whereas perfect aspect is marked by the auxiliary *ha* 'have,' followed by a form of the verb referred to as the 'supine.' For passive, there is both a morphological and a syntactic version, and a number of subtle factors influence the choice between the two. A paradigm for the verb *kittla* 'tickle.INFINITIVE' is provided in Example (2) (SG, singular; PL, plural; PRES, present; PERF, perfect; S PASS, BLI PASS, morphological and syntactic passive; FEM, feminine):

(2)	SINGULAR	PLURAL	PRESENT	PAST	PERFECT (PRES)	*-S* PASSIVE	*BLI* PASSIVE
1	jag	vi	kittlar	kittlade	har kittlat	kittlas	blev kittlad
2	du	ni					
3	hon(FEM)	de					

Noun phrases, on the other hand, have richer morphology, including agreement marking on modifiers. The masculine and feminine genders have merged into one, usually referred to as common gender (or *utrum*) and marked by *-n* in singular, which contrasts with neuter, marked by *-t*. In the plural and definite noun phrases, the gender distinction is neutralized. Definiteness is marked morphologically on nouns, and a singular count noun in its definite form can function as a referential noun phrase without any need for a syntactic determiner (see Examples (3a)–(3c)); without the definiteness marking, a syntactic determiner is required for the noun to function as a full noun phrase, as illustrated by Examples (4a) and (4b). When a modifier precedes the noun, a syntactic determiner is also required. In most cases, the noun retains its morphological marking, giving rise to so-called double definiteness, as Examples (5a)–(5c) show. Most modifiers show agreement with respect to gender (in singular indefinite), number, and definiteness. This is illustrated for definite noun phrases (Example (5)) and for indefinite ones (Example (6)). The definite–indefinite distinction on modifiers is commonly referred to as a weak–strong distinction in the literature. Case marking is found only on pronouns in Swedish (DEF, definite; COM, common; NEUT, neuter; INDEF, indefinite).

(3a) gris-en
pig-DEF.COM.
'the pig'

(3b) djur-et
animal-DEF.NEUT
'the animal'

(3c) gris-ar-na
pig-PL-DEF.PL
'the pigs'

(4a) en gris
a.COM pig
'a pig'

(4b) ett djur
a.NEUT animal
'an animal'

(5a) den ren-a gris-en
the.COM clean-DEF pig-DEF.COM
'the clean pig'

(5b) det hungrig-a djur-et
the.NEUT hungry-DEF animal-DEF
'the hungry animal'

(5c) de ren-a gris-ar-na
the.PL clean.DEF pig-PL-DEF.PL
'the clean pigs'

(6a) en ren gris
a.COM clean.COM.SG.INDEF pig
'a clean pig'

(6b) ett hungrig-t djur
a.NT hungry-NEUT.SG.INDEF animal
'a hungry animal'

(6c) två hungriga grisar/ djur
two hungry.PL pigs/ animals
'two hungry pigs/animals'

There is also a participle form, distinct from the supine, that is used attributively and predicatively and that agrees in gender and number, in a way similar to adjectives; this is illustrated in Examples (7a) and (7b) (PART, participle):

(7a) Brevet är skrivet
letter.DEF.NEUT be.PRES write.PART.NEUT
för hand.
by hand.
'The letter is written by hand.'

(7b) ett slarvigt skrivet
a.NEUT carelessly write.PART.NEUT.SG
brev
letter
'a carelessly written letter'

A striking property of Swedish is also that the possessive determiner exists in a reflexive and a nonreflexive form. The reflexive is used roughly in those environments in which a pronoun replacing the whole noun phrase would have to occur in its reflexive form. In Example (8a), then, *Björn* is eating someone else's sandwiches, whereas in Example (8b), he is eating his own sandwiches (POSS, possessive; MASC, masculine; REFL, reflexive):

(8a) Björn$_i$ äter hans$_j$ smörgåsar. [i ≠ j]
Björn eat.FIN POSS.MASC sandwich.PL
'Björn is eating his sandwiches.'

(8b) Björn$_i$ äter sina$_i$ smörgåsar.
Björn eat.FIN POSS.REFL.PL sandwich.PL
'Björn is eating his (own) sandwiches.'

The possessive reflexive agrees with its noun for number and gender much like an adjective; it does not, however, mark the gender of the possessor, unlike the nonreflexive form.

Like the other North Germanic languages, Swedish is a verb-second language. This means that main clause word order is built around the finite verb in the second position. The initial phrase will either be the subject or will have some special information structural status, such as topic or focus, or will be an adverbial phrase, often a so-called scene-setting adverbial phrase. Some examples are provided in the following sentences:

(9a) Philip gillar matematik.
Philip like.PRES mathematics
'Philip likes mathematics.'

(9b) Dinosaurier gillar Nils.
Dinosaur.PL like.PRES Nils
'Nils likes dinosaurs.'

(9c) Under sängen hittade Ellen
under bed.DEF find.PAST Ellen
inte några sockor.
not some sock.PL
'Ellen didn't find any socks under the bed.'

Any phrasal constituent can then precede the finite verb, including clauses, as illustrated in Example (10):

(10) Att han måste ha hjälm när
that he must have.INF helemet when
han cyklar gillar Robin inte.
he cycle.FIN like.FIN Robin not
'Robin does not like the fact that he has to wear a helmet when he cycles.'

The word order in the part of a main clause that follows the finite verb is usually described as relatively firm, with the order shown in Example (11):

(11) Main clause word order:
INITIAL CONSTITUENT → FINITE VERB → SUBJECT → ADVERBIAL → NEGATION → NONFINITE VERBS → OBJECTS/COMPLEMENTS

There is, however, some variation in word order also in this part of the sentence, motivated by factors such as information structure and scope. For instance, the subject *Robin* and the negation in Example (10) could change places.

The word order in subordinate clauses differs from that in main clauses in that the verb does not normally occur in second position, and it can only do so under certain very specific circumstances. Instead, the finite verb follows the subject and adverbials – in particular, the negation. The subordinate version of Example (9c) would then be as in Example (12):

(12) ...att Ellen inte hittade några
that Ellen not find.PAST some
sockor under sängen.
sock.PL under bed.DEF
'... that Ellen didn't find any socks under the bed.'

Naturally, there are many Swedish dialects, two of which deserve mention here. The first is the Swedish spoken natively in Finland: this dialect is quite distinct from the Swedish spoken in Sweden in phonology, lexicon, and syntax, one of the most striking differences being the lack of the two tones previously described (*akut accent* and *grav accent*). The other variety of Swedish of note is spoken in a small area roughly in the middle of Sweden; this dialect, *Älvdalen*, is closer to older forms of Swedish in that it preserves more morphological marking (for instance, case marking and agreement on the finite verb).

Sweden has long had a generous immigration policy and hence speakers of a large number of languages now live in Sweden. Though it is a controversial issue, there have been claims that a new variety of Swedish is emerging, namely, that spoken natively by children born in Sweden to parents who are not native speakers of Swedish. In the literature, a number of terms have been used to refer to this variety of the Swedish language, the most neutral being *Svenska på mångspråkig grund* 'Swedish on a multilingual basis.'

In 1786, *Svenska Akademien* 'The Swedish Academy' was set up to promote the purity of the language. The Academy continues to be responsible for publishing the major monolingual Swedish dictionary, *Svenska akademiens ordbok*, available online at www.saob.se. The Academy has also published a four-volume grammar of Swedish (see Teleman *et al.*, 1999). An excellent collection of corpora of Swedish, written and spoken, modern and historical, is publicly available at *Språkbanken* 'the language bank' at Gothenburg University (spraakbanken.gu.se).

Sweet, Henry (1845–1912)

M Cummings, York University, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

George Bernard Shaw, in the Preface to *Pygmalion* (1916), wrote of Henry Higgins that he was not a portrait of Henry Sweet, but that "there are touches of Sweet in the play." On the other hand, C. L. Wrenn, in his 1946 memorial of Sweet to the Philological Society, viewed "Shaw's *Pygmalion* as presenting in Professor Higgins a dramatic portrait of Sweet which is true in substance as well as showing many of his external qualities" (Wrenn, 2002: 529). Many regard Sweet as the greatest British linguist of the 19th century, a reputation he achieved in his own lifetime among continental scholars, but not at home.

Sweet was born into a middle-class family in London – his father was a barrister-at-law. His first experience of higher education was of Germanic philology at Heidelberg (1864). After a period in a business office, during which he became acquainted with Rask's *Anglo-Saxon grammar* and Alexander Melville Bell's *Visible speech*, he entered Balliol College, Oxford (1869). While still an undergraduate, he published for the Early English Text Society his edition of King Alfred's translation of Gregory's *Pastoral care* (1871). But, in 1873, he graduated with a fourth-class degree, marking the beginning of a series of academic rejections that colored his professional life. Two more significant early publications came quickly, his groundbreaking *History of English sounds* (1874) and *An Anglo-Saxon reader* (1876), which has persisted as a classic textbook in successive editions until the present day. These were followed by his unsuccessful application for the position of Chair of Comparative Philology at University College, London.

The period to 1885 saw a succession of further philological publications. The *Handbook of phonetics* (1877) marks the scientific beginning of the discipline. Five more books distinguished Sweet as Britain's leading Anglo-Saxonist: The *Anglo-Saxon primer* (1882), which, like the *Reader*, continues as a classic textbook, and his editions of *The Epinal glossary* (1883), King Alfred's translation of Orosius' *History* (1883), *Selected homilies of Ælfric* (1885) and *The oldest English texts* (1885). In the meantime he had also published his *First Middle English primer* (1884) and *Second Middle English primer* (1885). The same year saw the publication of the *Elementarbuch des gesprochenen Englisch*. He applied as a candidate for the Merton Professorship of English Language and Literature at Oxford and was once again passed over.

In the next 15 years, Sweet's attention was concentrated less on Old English studies and more on phonetics and grammar. His most notable productions include the *Primer of phonetics* (1890), the *Primer of spoken English* (1890), the *New English grammar* (1892, 1898), *The practical study of languages* (1899), and *The history of language* (1900). In the same period, among other works on Old English, is his *Second Anglo-Saxon reader, archaic and dialectal* (1887). In 1901 he made himself a candidate for the Oxford Professorship of Comparative Philology, and was yet again rejected by the academic establishment. However, the university did then appoint him Reader in Phonetics, which was to be his only academic posting. Before his death in 1912, he published *The sounds of English: An introduction to phonetics* (1908).

Many of those who knew him testify that Sweet was burdened all his life by a naïve outspokenness ('violent candour'; Wrenn, 2002: 516), which in later life, after so many disappointed attempts to achieve academic recognition, appeared as bitterness. Given the inherent conservatism of academic structures, together with the brilliant and pioneering nature of his own work, this acerbity may have been a factor in his long record of academic rejection. His career nevertheless was two careers: that of Anglo-Saxonist, and that of linguist. As an Anglo-Saxonist, he was the great pioneer of Old English dialectology, beginning with the apparatus in his 1871 edition of Alfred's Gregory. He also championed the viewing of historical linguistics in terms of the phonetic method. As a linguist, he was the creator of scientific phonetics, and seems (by 1877) to have anticipated Jan Baudouin de Courtenay's elucidation of the phoneme concept, although without that term. Sweet's 'broad Romic' notation served as the original basis for the IPA alphabet.

One of the most important purposes for which human beings use language is to describe a sequence of related events, for example, in telling a story, reporting what happened, making plans, or explaining how to do something. The term 'switch-reference' refers to one of the ways available in some languages of the world for specifying the links between events in discourse sequences such as these. The 'switch-reference system' of such a language provides its speakers with a set of verb markers from which they must choose, to indicate whether or not the events share the same major protagonist. Often the switch-reference system also enables speakers to distinguish other ways in which the events may be related, for example, with respect to their setting in time or space or a causal connection between them. The precise definition of switch-reference has been considered a difficult and controversial question. This is partly because the grammatical systems which the term has been used to label differ in their formal characteristics depending on whereabouts in the world the language is spoken, and partly because it has been hard to provide a precise and general delimitation of the meanings and functions of switch-reference systems.

Switch-Reference

The term 'switch-reference' was coined by William Jacobsen (Jacobsen, 1967). He used it to describe

Switch-Reference

One of the most important purposes for which human beings use language is to describe a sequence of related events, for example, in telling a story, reporting what happened, making plans, or explaining how to do something. The term 'switch-reference' refers to one of the ways available in some languages of the world for specifying the links between events in discourse sequences such as these. The 'switch-reference system' of such a language provides its speakers with a set of verb markers from which they must choose, to indicate whether or not the events share the same major protagonist. Often the switch-reference system also enables speakers to distinguish other ways in which the events may be related, for example, with respect to their setting in time or space or a causal connection between them. The precise definition of switch-reference has been considered a difficult and controversial question. This is partly because the grammatical systems which the term has been used to label differ in their formal characteristics depending on whereabouts in the world the language is spoken, and partly because it has been hard to provide a precise and general delimitation of the meanings and functions of switch-reference systems.

Switch-Reference

The term 'switch-reference' was coined by William Jacobsen (Jacobsen, 1967). He used it to describe

systems in Native American languages that indicate relationships of identity or difference between participants playing similar roles with respect to successive narrated events. In a description of the Hokan-Coahuiltecan family of Native American languages, he gave the much-quoted definition: "Switch-reference consists simply in the fact that a switch in subject or agent (...) is obligatorily indicated in certain situations, by a morpheme, usually suffixed, which may or may not carry other meanings in addition" (Jacobsen, 1967: 240).

Example (1) illustrates the switch-reference system found in the Native American language Mojave (Mohave) (Munro, 1980: 145):

(1a) nya-isvar-k iima-k
when-sing-SS *dance-TENSE*
'when he_i sang he_i danced'

(1b) nya-isvar-m iima-k
when-sing-DS *dance-TENSE*
'when he_i sang he_j danced'

The Mojave switch-reference system consists of two morphemes, *-k* and *-m*, which are suffixed to the verb of an adverbial clause such as 'when he sang' in order to indicate whether the subject of that clause is the same as the subject of the following main clause. If *-k* is used, the same reference is indicated, whereas if *-m* is used, a different reference is indicated.

The abbreviations SS and DS in example (1) are commonly used to indicate the 'same subject' (or coreference) marker and the 'different subject' (or disjoint reference) marker in the switch-reference system. The two clauses related by switch-reference are also distinguished terminologically. The clause containing the verb with switch-reference marking (*nya-isvar-k/m* in (1)) is normally referred to as the 'marked' or 'dependent' clause, and the other clause (*iima-k* in (1)) is called the 'controlling,' 'independent,' or 'referential' clause. Jacobsen (1983: 152–154) gives a historical survey of terminological variants.

Recently, the term 'switch-reference' has come to be used in a more general sense by some researchers to refer to the referential relationship between sequentially ordered subjects in discourse in languages such as Spanish, where choice between an overt pronoun subject and a null subject often seems related to whether there has been a switch in subject reference. We will not be concerned with this usage of the term here, but will restrict ourselves to consideration of switch-reference systems as traditionally defined, that is, those that are morphologically marked on non-nominal expressions and clearly form a grammatical subsystem of the language.

The Distribution and Origins of Switch-Reference Systems

As well as being found in numerous North American languages, with respect to which it was first described, switch-reference systems have been identified in South America, in many of the non-Austronesian languages spoken in Papua New Guinea, and in numbers of Australian and African languages. Outside these areas, so far relatively isolated reports of switch-reference have been made, for a small number of Austronesian, Caucasian, Turkic, and Asian languages.

General articles on the distribution and typological characteristics of switch-reference can be found for North America (Jacobsen, 1983), Australia (Austin, 1981), Africa (Wiesemann, 1982) and Papua New Guinea (Roberts, 1997) (see also Stirling, 1993 for a general typological survey). Examples of the North and Central American language families for which switch-reference systems have been described include Hokan-Yuman, Muskogean, and Uto-Aztecan languages, and Jacobsen (1983) describes them as stretching chiefly across the Southwest and Great Basin regions and including areas of California. In South America, there is a broad areal scattering of switch-reference with language families including Quechuan, Panoan, and Tupi-Guaranian. In Australia, languages with switch-reference stretch from the West Coast across to Queensland, and include Warlpiri, Diyari (Dieri), Mparntwe Arrernte, Pitjantjatjara, Yankunytjatjara, Dalabon (Ngalkbun), and Alyawarra (Alyawarr). In Africa, most work has been done on Bantu languages of the Grasslands region of Cameroon, such as Bafut and Noni (Noone), but switch-reference has also been identified in Lango, spoken in Uganda. The most extensive areal survey to date has been done by Roberts (1997) for Papua New Guinea. He surveys 169 languages of which 122 (72%), from at least 51 families, are found to have switch-reference systems, and on this basis suggests that Papua New Guinea is home to the most concentrated and diverse collection of languages with switch-reference in the world (Roberts, 1997: 102).

Austronesian languages identified as having switch-reference include one in Papua New Guinea, Dami (Marik) (Roberts, 1997: 114), and a number of languages of Vanuatu, of which the best described is Lenakel (Lynch, 1983). In Eurasia, the Caucasian languages include Chechen, Ingush, Lak, and Darga (Nichols, 1983), Turkic languages are represented at least by Tuva (Tuvin), and switch-reference has also been identified for Nivkh, spoken in the Sakhalin region (Bergelson and Kibrik, 1995).

Isolated examples of other languages have from time to time been described as having switch-reference, or at least something functionally akin to it, and the list presented here is representative rather than comprehensive.

Switch-reference is a type of grammatical phenomenon subject to areal diffusion, that is, switch-reference systems tend to be found in geographically adjacent languages, which need not be related genetically and which may differ in the way the switch-reference relation is marked. This has been shown for Native American languages (Jacobsen, 1983) and for Australian languages (Austin, 1981) and is discussed by Roberts (1997) for the Papuan languages of Papua New Guinea, where he correlates presence of switch-reference, which is found mostly in the mountainous highland regions, with the Trans New Guinea Phylum, but also describes a number of cases where genetically unrelated languages have acquired switch-reference systems apparently under the influence of their neighbors.

Across languages, the origins of switch-reference morphemes are diverse. For particular languages or language groups, the origins of the morphemes may be suggested by their homophony with other grammatical markers in the language. For most Australian languages and some Native American languages, switch-reference morphemes are related to nominal case inflections, with SS marking being associated with nominative or ergative case and DS marking associated with locative or allative case (Austin, 1981). Switch-reference markers may also be derived from verbal agreement markers; tense, aspect, or modality markers; subordinating clitics or conjunctions; and a number of other sources.

The grammatical phenomena identified as switch-reference in these geographically and genetically diverse languages share the characteristic that for some types of syntactic relation between clauses in the language, a choice of morphemes is obligatorily made and used to indicate reference relations between nominal arguments in the two clauses thus related. These morphemes are situated not on the nominal arguments thus related but on the verb, or more rarely, they appear as independent morphemes, normally in the position for clausal clitics or conjunctions. However, there are some characteristic differences between the types of systems that are found in different regions, and the more important of these will be discussed in 'Typological Characteristics of Switch-Reference Languages' and 'Problems of Definition: The Functions of Switch-Reference Systems.'

Typological Characteristics of Switch-Reference Languages

The Formal Marking of Switch-Reference

The majority of switch-reference languages are head marking, freely allow omission of arguments, and lack elaborate gender or noun class systems. For most languages with switch-reference systems, the order of the major clausal constituents follows the pattern subject-object-verb (SOV). Languages with this pattern of clausal constituent ordering tend to prefer suffixation to prefixation and generally order modifiers before heads; hence syntactically dependent clauses come before independent main clauses. For this reason, in most languages with switch-reference systems the marking is by suffixation on the verb of a syntactically dependent clause that precedes the controlling clause. When switch-reference occurs in a language which does not have SOV constituent order, the ordering characteristics of the switch-reference marking also alter. For example, the Austronesian language Lenakel has SVO constituent ordering, and switch-reference is by prefixation, with the switch-reference-marked clause following the independent main clause.

Crosslinguistically, the SS marker is consistently the unmarked coding choice: it is typically morphologically less complex and may be zero-marked in opposition to overtly marked DS, or the DS marker may require the presence of additional overt indication of the referent (e.g., an overt full NP or extra agreement marking), whereas SS marking often occurs with a zero subject.

The Syntactic Relation between the Two Clauses

The switch-reference relation holds between two clauses that are syntactically related and, normally, linearly adjacent; some languages allow 'clause-skipping,' where, for example, a sequentially ordered set of subordinate clauses may all be marked with respect to a final main clause, so that some of these are not strictly adjacent to their controlling clause (e.g., Chickasaw; Walker, 2000). The controlling clause is never syntactically subordinate to the marked clause.

Crosslinguistically, there are two major types of syntactic relation in which the two clauses may stand. The first is where the marked clause is subordinate to the controlling clause. It may be an adverbial clause, a complement clause, a relative clause or an 'adjoined relative clause' of the kind found in Australian languages. This type of relation is most

prevalent in the switch-referencing languages of North America and Australia. The second type is where the marked clause and the controlling clause are in a looser relation of clause chaining, parataxis, or conjunction. In clause chaining constructions, a string of dependent medial clauses is followed by a final independent clause. The medial clauses are marked for switch-reference but lack some or all of the verbal inflection characteristic of independent clauses, such as tense, mood, and agreement. The final clause is not marked for switch-reference but does have finite verb inflection, and this is assumed to apply to the entire clause chain. Clause chains may be very long; up to 20 clauses per chain have been noted in the literature. This second type of relation between switch-reference clauses is characteristic of Papuan languages. Example (2) is from the Papuan language Amele (Roberts, 1997: 104):

(2) ija Malolo uqa=na ka jic ana-g
1SG Malolo 3SG=of car road mother-3SG.POSS
ono=nu sum-udi
there=for wait-3s.DO(SS)
ne-ce-b tobo-co-min
come.down-DS(SEQ)-3SG climb.up-DS(SEQ)-1SG
bi-bil-igin
DUR-sit-1SG.SIM.DS
bel-ow-an
go-1DU-YESTP
'As I waited there (yesterday) on the main road for Malolo's car he came down and I climbed in and off we went.'

The abbreviations SIM and SEQ stand for 'simultaneous' and 'sequential' temporal relations between the event described by the clause so marked and the event described by the following clause. 'Problems of Definition: The Functions of Switch-Reference Systems' below discusses the incorporation of such meaning distinctions into switch-reference systems.

Switch-reference marking is normally restricted to some subset of the range of clause linking syntactic relations the language exhibits. Within the switch-reference-marked range of relations, switch-reference systems may distinguish distinct pairs of morphemes corresponding to different types of syntactic relations between the two clauses (distinctions are also made on the basis of secondary meanings, as discussed in the next section). For example, Chickasaw has distinct pairs of SS and DS markers for clauses in subordinate as opposed to paratactic relations. Thus, choice of a particular switch-reference morpheme may indicate the type of syntactic relation between the two clauses as well as the other functions it has.

Problems of Definition: The Functions of Switch-Reference Systems

All languages have ways of 'tracking the reference' of nominal arguments through a stretch of discourse, and most have ways of distinguishing continuity from discontinuity of major arguments in syntactically related clauses. For example, in English a repeated subject in a subordinate or conjoined clause is typically omitted, while a new subject is given overt expression. Switch-reference has been seen as belonging to this broad functional category of reference tracking or topic continuity (Givón, 1983), and the desire to distinguish switch-reference from other devices for tracking the reference of nominal arguments through the discourse has led to a concern with definitional issues. Thus in 1981, a major symposium on switch-reference was held at Winnipeg, Canada, and took as its goal the delimitation of switch-reference and identification of its parameters of variation cross-linguistically (Haiman and Munro, 1983; see also Foley and Van Valin, 1984).

Two ways in which switch-reference is clearly distinguishable from other reference tracking devices are that switch-reference is marked not on the nominal arguments whose reference is tracked, but elsewhere in the clause, and that switch-reference morphemes must occur regardless of whether they are actually required for disambiguation of reference, i.e., when the two NPs related are both third person.

A narrow general definition of the function of switch-reference marking that has been assumed quite widely is that the switch-reference morphemes indicate obligatory coreference or disjoint reference between the subject NPs of the two clauses in the switch-reference relation. Henceforth the term 'pivot' will be used to identify the nominal arguments that are related as having coreference or disjoint reference by the switch-reference marking. This characterization thus restricts the domain of the switch-reference relation to pivots in a particular grammatical function, that of subject, and restricts the relation indicated to that of referential binding. Such a definition highlights the exotic nature of switch-reference, as marking information about nominal reference via a verbal category (Haiman and Munro, 1983: ix).

Although pervasive, such a characterization of switch-reference fails to capture its functional complexity, as is shown in 'The Pivot NPs and the Referential Relation Between Them' and 'Nonreferential Functions of Switch-Reference Systems.' More recent general characterizations of the function of

switch-reference systems have tried to accommodate the whole range of its functions crosslinguistically. Switch-reference is seen as having the clause as its domain and as expressing a relationship between two clauses or between the events described by two clauses, which indicates continuity or discontinuity between them along a number of parameters. The most important parameter is reference of the major protagonist, but other parameters may be distinguished, such as the temporal and spatial location of the event and its status as having actually occurred or not (Roberts, 1988; Ariel, 1990; Stirling, 1993; Huang, 2000). The fact that switch-reference is not marked on nominal arguments reflects the fact that it provides information about the clause as a whole.

The Pivot NPs and the Referential Relation Between Them

Examples of switch-reference systems that relate not only subjects but also NPs in other grammatical functions have been identified in a few Native American languages including Capanahua, a Panoan language spoken in Peru (Jacobsen, 1967), and in a number of Australian languages including Warlpiri (Simpson and Bresnan, 1983). Capanahua is notable because nonsubject arguments in both the marked and the controlling clause are important: it has six DS suffixes, two of which imply the identity of the subject of the marked clause with the object of the controlling clause, and one of which implies the identity of the object of the marked clause with the subject of the controlling clause. Better described is the Warlpiri system, where the subject of a switch-reference-marked infinitival clause is related by the switch-reference marking to some argument of a preceding controlling clause. The four Warlpiri switch-reference morphemes and their functions are listed below:

–*karra*: the subject of the marked clause is coreferential with the subject of the controlling clause.
–*kurra*: the subject of the marked clause is coreferential with the object of the controlling clause.
–*rlajinta*: the subject of the marked clause is coreferential with that of the controlling clause, and the event described by the controlling clause is an **accidental** consequence of the event described by the marked clause.
–*rlarni*: the subject of the marked clause, if not overt, is the same as the oblique dative argument of the controlling clause.

For some other languages, it has been argued that the definition of the switch-reference pivot should not be strictly the syntactic subject but should appeal to notions of agentivity or topicality of noun phrases. A key set of examples here are those where the controlling clause is an impersonal construction or some other construction with a 'referentially deficient' subject (such as inalienably possessed body parts or weather constructions). In such cases, the switch-reference marking is often SS, even though technically the subjects of the two clauses are not coreferential, reflecting the continuation of the major relevant protagonist. That is, typically the switch-reference system uses DS marking for a new agentive, fully referential subject and SS marking to indicate that no new agentive, fully referential subject has been introduced. Exactly how this is described depends on the language and the researcher, with claims being made variously that for some languages the switch-reference pivot may be required to be not merely the syntactic subject, but agentive as well (Stirling, 1993); more rarely that switch-reference operates simply in terms of the agent of the clause, whatever grammatical function it fulfills; or that the switch-reference pivot should be defined as the topic of the clause. For Barai (Olson, 1981), it is argued that there are two switch-reference systems, one of which operates in terms of grammatical subject and one in terms of topic.

Whether the pivot NPs are defined in terms of grammatical function, semantic role, or discourse status, the relation between them may be complicated if they are neither strictly identical nor completely different, that is, where the reference of one NP includes that of the other or they overlap in reference (Wiesemann, 1982; Stirling, 1993). Such a situation typically occurs where the inclusive NP is plural and the other NP identifies some member(s) of the set, but also includes cases where there is a part–whole relationship between the referents of the two NPs. In such cases, a range of strategies is found crosslinguistically, and it may be relevant whether the inclusive NP is in the marked or controlling clause, with the possible relations of referential overlap listed below.

(a) Marked-NP includes Controlling-NP
(b) Marked-NP is included in Controlling-NP
(c) Marked-NP overlaps with Controlling-NP.

Although reportedly there are languages where all these cases require DS marking (e.g., Pima, Huallaga Quechua), crosslinguistically, SS marking is frequently used for cases of referential overlap, either as a requirement of the grammar or optionally on the basis of the way the speaker chooses to present the events. In some languages, including many North American and some Papuan and Australian languages, it makes no difference whether the inclusive NP is in the marked or controlling clause; SS marking

is general (Huichol, Martuthunira Martuyhunira) or possible (Maricopa, Mojave) in either case. In other languages, including many Australian and Papuan languages, SS marking is restricted to cases where the inclusive NP is in the marked clause (a); if the relation of inclusion is the other way around with the inclusive NP in the controlling clause, and (b), DS marking must be used (Diyari, Amele, Ono, Suena). The reverse does not generally occur, i.e., SS marking allowed just when the inclusive NP is in the controlling clause, although it has been reported for a few languages such as Yankunytjatjara. Sometimes the relation of inclusion may be determined by cultural factors such as kinship relations rather than simply by referential relations (as in Mparntwe Arrernte; Wilkins, 1988: 166), and in some cases the person of the pivot NP is relevant to whether SS or DS is used, with agreement in person or presence of first person, making SS marking more likely. A few languages solve the problems of referential inclusion by using both SS and DS marking at the same time on the same verb (Irumu: Tuma-Irumu; Roberts, 1997).

Nonreferential Functions of Switch-Reference Systems

Switch-reference systems frequently offer more than one pair of morphemes to choose from, and the additional meaning typically concerns the temporal relation between the two events. The most common distinction is whether these events occur simultaneously or in temporal sequence. (Example (2) in 'The Syntactic Relation Between the Two Clauses' illustrated a system with such a distinction.) In this respect, switch-reference systems can be compared to other verbal morphology whose sole function is to distinguish simultaneous from sequential events, as in Swahili, where the prefix *ka-* indicating a sequence of consecutive events is contrasted with the prefix *ki-*, which indicates interrupting contingent or simultaneous events (Hopper and Thompson, 1980: 281). Other meanings may be associated with particular choices in a switch-reference system as well. These tend to concern logical or epistemic relations between the events, involving notions of expectation, causality, purpose, condition, and contrast.

In addition, in many switch-reference languages the DS marker may be used even though the switch-reference pivots are coreferential, to indicate a discontinuity in some other parameter of the event sequence being described. For example, the events may differ in spatial location, in temporal location, in whether they actually occurred, or in whether they have an agentive controller. A crosslinguistic survey of such cases is given in Stirling (1993) and they are discussed in a range of works including Roberts (1988). Apparently anomalous DS marking may also be used to indicate the beginning of a new discourse unit (Stirling, 2001).

Theories of Switch-Reference

A number of theories of switch-reference have been proposed within the domains of syntax, semantics, and pragmatics.

Finer (1985) proposed a formal grammar of switch-reference within a version of government binding theory called generalized binding. His account was based on a subset of switch-reference systems from Native American languages and was a formal encoding of the view that switch-reference is a relation between subject NPs that happens to be mediated by other elements of the clause. He assumed that switch-reference is a syntactic relation to be accounted for by the binding theory in an analogous way to reflexive pronouns. Information about switch-reference starts off encoded in an abstract operator in the ultimately unrealized constituent of COMP, with the SS marker treated as a generalized anaphor, while the DS marker is seen as a generalized pronominal; the syntactic–semantic information encoded by the abstract operator percolates through to the subject nominals of the two clauses and has the effect of marking them with identical or disjoint referential indices, while the phonological information affects the realization of the verb.

Following on from Finer's account, a number of treatments of switch-reference have been proposed in more recent approaches to generative grammar, including the principles and parameters approach and the minimalist program (Nichols, 1999; Broadwell, 1997; Watanabe, 2000; Déchaine and Wiltschko, 2002). While these differ in detail, all accounts proposed within Chomskyan syntactic frameworks crucially make the assumption that switch-reference is universally a purely structural local relation marked on a subordinate clause and best accounted for in terms of configurational properties of the sentence and c-command relations. Broadwell (1997) considers data from clause chaining languages, which appear to offer significant counter-examples, and argues that they can be reanalyzed as subordination: a key issue for the viability of these approaches is thus the syntactic status of medial clauses within clause chaining languages, and it remains controversial as to whether they can be assimilated to syntactic subordination, with most researchers working on these languages remaining skeptical (cf. Roberts, 1997). Chomskyan syntactic accounts have so far made no attempt to handle nonlocal switch-reference relations and referential overlap or other functional

complexities discussed in 'Problems of Definition: The Functions of Switch-Reference Systems.'

Tsujimura (1987) proposed a theory for switch-reference within the framework of categorical grammar. She formalized the insight that SS can be considered as 'agreement' and DS as 'disagreement.' She showed how her account can handle the switch-reference systems of Tairora, Hopi, and Warlpiri. In particular, she provided an account for switch-reference systems which mark reference relations involving nonsubject NPs.

In Stirling (1993), a formal theory of the syntax and semantics of switch-reference was proposed within the framework of unification categorial grammar, which associates a syntax based on categorial grammar with a semantics based on discourse representation theory. This account formally encoded the idea that switch-reference has the clause as its semantic domain and indicates agreement or disagreement between parameters of the events described by the clauses it relates, most importantly referential relations between major protagonists but also other parameters. The formal treatment was illustrated with an account of the switch-reference system of the Papuan language Amele, and was claimed to generalize to a range of switch-reference systems, in particular clause chaining systems and systems with complex nonreferential functions.

Huang (2000) suggests a way of incorporating some of the insights of Stirling (1993) within his neo-Gricean pragmatic theory of anaphora: any speaker who intends to indicate continuity of the eventuality (including coreference of pivots) will use SS marking; use of DS marking will generate implicatures to the effect that some change must be at issue.

Considerable work has also been done on switch-reference and related phenomena within the framework of lexical functional grammar, as part of a general theory of anaphoric binding and control (Simpson and Bresnan, 1983; Dalrymple, 1993).

Related Phenomena

The term 'obviation' has been used to describe switch-reference systems of the Warlpiri type, which tracks other arguments in the clause as well as subjects (Simpson and Bresnan, 1983). Simpson and Bresnan see this system as part of the more general phenomenon of 'control,' i.e., restrictions on the interpretation of unexpressed arguments in a syntactically dependent clause in terms of the interpretation of arguments in the main clause. Obviation systems are ones that exclude certain possible controllers.

This use of the term 'obviation' should be distinguished from its use in work on Algonquian languages, in which personal pronoun systems make a distinction between a 'proximal' third person, which is central to the discourse, and an 'obviative' third person (also called a 'fourth person'), which is peripheral to the discourse.

Similar to both obviation and switch-reference are 'logophoric' systems. In these, a NP in a dependent clause takes a special pronominal form to indicate its coreferentiality with a NP in a controlling clause. The dependent clause is constrained semantically to be a context of reported speech or mental or psychological state. Switch-reference and logophoric systems may cooccur in the same language.

Switch-reference marking of the clause chaining type is related in complex and interesting ways to 'serial verb' constructions.

Future Work

Detailed descriptive work on switch-reference languages at the discourse level remains limited, but would be highly desirable so that the interaction between the choice of switch-reference morpheme and semantic, pragmatic, and stylistic factors may be properly determined. For example, Walker's (2000) study of switch-reference in Chickasaw conversation, illustrated switch-reference markers being used even in the course of code-switching between Chickasaw and English. Continued work on more fully comprehensive typological and syntactic studies would also be beneficial.

Switzerland: Language Situation

H Bickel, University of Basel, Basel, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

Switzerland, surrounded by Germany, France, Italy, Austria, and Liechtenstein, is a small central European state with 7.3 million inhabitants (80% of whom have Swiss citizenship) and a total area of 41 293 km^2. Its geographical centre lies in the central alpine massif; the larger cities and the industrial centers are situated in the northern plateau, in the so-called Mittelland (Geneva, Lausanne, Berne, Zurich), and north of the Jura chain (Basel).

There are four national languages in Switzerland, each of which is spoken in a different area: German in northern, central and eastern Switzerland, French in the west, Italian in the area south of the Alps, and Romansch in the alpine southeast (**Figure 1**).

According to the most recent census, Switzerland has the following language distribution: German 63.9%, French 19.5%, Italian 6.6%, Romansch 0.5%, and others 9.5%. Around 20% of Switzerland's population is foreign (including nonnaturalized Swiss-born descendants of immigrants), which accounts for the fact that some foreign languages (e.g., Serbo-Croatian and Turkish) are more strongly represented than the national language Romansch.

The German-Speaking Area

Historically, from the late Middle Ages, Switzerland comprised a confederation of German-speaking cantons or states that ruled a couple of French- and Italian-speaking territories. Only following the influence of French revolutionary ideas and an invading French army (1798), and finally after the foundation of the modern federal state (1848), did Switzerland officially become a multilingual country.

With a share of 63.9%, the German-speaking population is by far the largest language group in Switzerland. Within Europe, however, the German-speaking Swiss constitute only a small minority,

Switzerland, surrounded by Germany, France, Italy, Austria, and Liechtenstein, is a small central European state with 7.3 million inhabitants (80% of whom have Swiss citizenship) and a total area of 41 293 km^2. Its geographical centre lies in the central alpine massif; the larger cities and the industrial centers are situated in the northern plateau, in the so-called Mittelland (Geneva, Lausanne, Berne, Zurich), and north of the Jura chain (Basel).

There are four national languages in Switzerland, each of which is spoken in a different area: German in northern, central and eastern Switzerland, French in the west, Italian in the area south of the Alps, and Romansch in the alpine southeast (Figure 1).

According to the most recent census, Switzerland has the following language distribution: German 63.9%, French 19.5%, Italian 6.6%, Romansch 0.5%, and others 9.5%. Around 20% of Switzerland's population is foreign (including nonnaturalized Swiss-born descendants of immigrants), which accounts for the fact that some foreign languages (e.g., Serbo-Croatian and Turkish) are more strongly represented than the national language Romansch.

The German-Speaking Area

Historically, from the late Middle Ages, Switzerland comprised a confederation of German-speaking cantons or states that ruled a couple of French- and Italian-speaking territories. Only following the influence of French revolutionary ideas and an invading French army (1798), and finally after the foundation of the modern federal state (1848), did Switzerland officially become a multilingual country.

With a share of 63.9%, the German-speaking population is by far the largest language group in Switzerland. Within Europe, however, the German-speaking Swiss constitute only a small minority,

Figure 1 Map showing distribution of languages in Switzerland.

compared with 80 million German-speaking Germans and eight million German-speaking Austrians.

In German-speaking Switzerland there is a profusion of distinct Alemannic dialects, collectively called *Schweizerdeutsch* (Swiss German) (Alemannisch). A characteristic feature of the language situation is diglossia, the use of dialect and Standard German side by side. Standard German is used for most written functions and such highly formal spoken genres as public lectures or university and school teaching, whereas local dialects are used for almost all other spoken purposes. Swiss Standard German is quite similar but not identical to Standard German as it is used in Germany or Austria. There are differences on all linguistic levels, i.e., on the phonetic, morphological, syntactic, and especially the lexical levels. These differences are summarized under the term 'Helveticism.' They are typical of the Swiss variety of the pluricentric German standard language.

The French-Speaking Area

French-speaking Switzerland (called 'Romandie') with roughly 1.4 million speakers is the only linguistic area in Switzerland where dialects (called 'patois') are of almost no importance anymore. Romandie is part of the wider French language community and has widely adapted to the central French language policy. This policy aimed to standardize French grammar, lexicon, and pronunciation, which weakened the regional French languages and dialects considerably. Hence, the dialects of French-speaking Switzerland, which mostly belonged to the Franco-Provençal language, have pretty much died out. At a rough estimate, only 1% to 2% of the population still have some knowledge of their local dialect, mostly of them living in Catholic regions, i.e., the cantons of Valais, Fribourg, and the Jura.

The decline of the dialects is also due to negative stereotypes towards all deviations from the standard French of the Ile de France, with Paris as its center, which generally prevails in the French-speaking areas. In Switzerland, the decline of dialects started in the 17th century, at first in the Protestant cities of Geneva and Neuchâtel, and finally began to spread to the countryside with increasing speed after the French revolution. Since the first half of the 20th century, the use of patois has been forbidden in the schools of French-speaking Switzerland. Colloquial standard French gradually took the place of the patois.

Similar to the situation in the German-speaking area, the standard French spoken in Switzerland has some national and regional differences compared to the French spoken in France. Some of these differences derive from older French norms, others are influenced by former dialects, and a relatively small number are borrowings from German. With the 1997 publication *Dictionnaire suisse romand: particularités lexicales du français contemporain* by André Thibault these differences have been officially codified. Thus, French-speaking Switzerland is a national center of the pluricentric French language.

The Italian-Speaking Area

Approximately 550 000 inhabitants speak Italian as their first language. Around half of them are Italian immigrants, who have settled in all the linguistic areas of Switzerland, while the other half, Italian-speaking Swiss, mostly live south of the Alps in the cantons of Ticino and Grigioni. The linguistic repertoire of the Italian-speaking Swiss population includes local dialect, regional dialect, regional Italian and standard Italian. The dialects are part of North Italian Lombardic (Lombard). Until the 1970s, their local dialect was the first language for the majority of Italian-speaking Swiss. After that, young people gave up their dialect for regional Italian, mainly in the industrial centers of southern Ticino.

Standard Italian was rarely used for oral communication until the middle of the 20th century. It was used mainly as a written language. Comparable to German in German-speaking Switzerland, it was spoken only in highly formal situations, such as political assemblies, public lectures, or funerals. Lack of practice led to an attitude of reserve and insecurity in using standard Italian. This has changed only in the past 30 years.

The Romansch-Speaking Area

The Romansch-speaking population is the smallest language group in Switzerland, containing fewer than 50 000 persons, who live predominantly in the numerous valleys of the canton of Graubünden (Grisons/Grigioni). The language territory of the Romansch-speaking population is not continuous any more but is interspersed with German-speaking areas. As the majority of the Romansch population is bilingual (Romansch/German), the number of Romansch speakers is generally decreasing. In contrast to the other national languages, Romansch is not supported by a larger language community outside Switzerland. Other than within national borders, it is spoken only in a few linguistic enclaves of northeast Italy. Therefore the Romansch language is threatened by extinction.

The isolation of the alpine valleys led to the development of five distinguishable idioms (Sursilvan, Sutsilvan, Surmiran, Puter, and Vallader), each of them with its own written conventions. In 1982 an artificial single written language for all five idioms, known as Rumantsch Grischun, was created to try to stop the erosion process.

Multilingualism

In Switzerland, only a small minority of the population is genuinely multilingual. The knowledge of further national or foreign languages is normally acquired at school. Until the end of the 20th century, all schoolchildren had to learn at least one additional national language. Now, in view of the increasing importance of English as a world language, English is taught at all school levels as an additional language. In some cantons of the German-speaking area, English has recently become the first additional language to be taught at primary and secondary school, with French following as a second additional language.

Syllabic Constituents

S Davis, Indiana University, Bloomington, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

The term 'syllabic constituents' refers to the subgrouping of segments within the syllable. The issue of whether the syllable contains such constituents has been controversial among phonologists. One view is that the syllable has no internal constituents but consists of the segments themselves (Kahn, 1976; Clements and Keyser, 1983). Another view divides the syllable into three constituents: onset, nucleus, and coda (Hockett, 1955; Haugen, 1956; Davis, 1988). The onset is a constituent comprising the syllable-initial consonant or consonant cluster; the nucleus consists of the vowel or syllabic consonant and is considered the peak of the syllable; and the coda contains the syllable-final consonant or consonant cluster. Under this view, the nucleus is an obligatory constituent of the syllable. A third view posits a bipartite division of the syllable into onset and rhyme (or 'rime'), where rhyme comprises the syllable peak (usually a vowel) and any postpeak consonants within the syllable. While the onset-rhyme division is attributed to Pike and Pike (1947), arguments for the division are provided by Halle and Vergnaud (1980) and Selkirk (1982). Proponents of rhyme structure disagree as to whether the rhyme formally consists of the labeled constituents, nucleus and coda. A more minimalist view of syllable constituents can be found in the moraic approach to the syllable as developed in the work of Hayes (1989), in which morae alone comprise the constituents of the syllable.

A wide variety of evidence has been presented to argue for syllabic constituents. Possibly the strongest evidence for the division into onset, nucleus, and coda (as well as rhyme) comes from phonotactic constraints. Other evidence for this division can be gathered from allophonic distribution as well as from phenomena such as speech errors and language games. On the other hand, evidence from syllable weight has been provided to motivate the moraic view of the syllable.

First, phonotactic constraints, often viewed as the primary evidence for syllabic constituents, are those constraints found on the sequence of segments in a given language. Many phonologists (Fudge, 1969; Selkirk, 1982) have noted that in English, there are constraints holding over the first two phonemes of a syllable if both are consonants. For example, if two consonants appear at the beginning of the syllable, they cannot both be sonorant consonants. But, there are virtually no constraints if the first two phonemes of a syllable consist of a consonant followed by a vowel. The constraints holding over the first two consonants suggest that they comprise a single unit or constituent, the onset, while the lack of such constraints over a consonant followed by a vowel indicates that they are in separate parts of the syllable. On this view, the domain of phonotactic constraints is the syllabic constituent. Phonotactic arguments have been given by Selkirk (1982) to argue for the constituency of the nucleus and coda in English. For example, the constraints that hold between the vowel and a following offglide in English (e.g., [ay] is a possible sequence but not [ew]) argue for their comprising the peak (or nucleus) of the syllable, and the restrictions that hold among the consonants in consonantal sequences at the end of a syllable (e.g., they cannot be of rising sonority) argue for the constituency of the coda. Furthermore, the argument from phonotactic constraints has been used to justify the rhyme as a constituent of the syllable. Researchers such as Halle and Vergnaud (1980) and Selkirk (1982) have observed that there are restrictions on what nucleus can precede what coda. In an English syllable containing a diphthong followed by a consonant cluster, the consonant cluster must consist of coronal consonants (e.g., 'kind' [kaynd] vs. the phonotactically impossible *[kaymp]).

An important issue that arises in the use of phonotactic constraints as a diagnostic for syllabic constituency concerns the particular nature of the phonotactic constraint. Davis and Hammond (1995) specifically argue against the use of phonotactic constraints that reference identity, OCP-type constraints, as a diagnostic for constituency. They note that these may hold between adjacent or nonadjacent phonemes that do not otherwise seem to comprise a single constituent. Both Davis and Hammond (1995) and Blevins (1995) note that it is sonority-based phonotactics that are the diagnostics. As observed by Blevins, in an English CCV sequence, the sonority value of the second consonant is restricted by the first one, not by the following vowel, thus suggesting that the first two consonants comprise a constituent. Another issue that arises in the discussion of the phonotactics of English and other languages is the patterning of s-clusters. For example, English syllables can begin with /sp/, /st/, and /sk/, but there are no non-s-obstruent clusters at the beginning of the syllable. This evidence has led to suggestions that these s-clusters in English are phonologically single segments (Selkirk, 1982), but they could just as well be analyzed with the initial /s/ of the cluster phonologically outside of the syllable.

A second type of evidence bearing on syllabic constituents comes from allophonic distribution, namely the distribution of the variant pronunciations of a phoneme. It is not uncommon for allophones of a phoneme to be associated with certain positions within the syllable. Consider, for example, one pattern of the distribution of light and dark (velarized) /l/ in American English. Light /l/ occurs at the beginning of the syllable and as the second consonant in a syllable-initial consonant sequence (e.g., as in 'play'). Dark /l/ occurs at the end of the syllable and as part of a syllable-final consonant sequence (e.g., as in 'help'). One way to account for this distribution is by reference to syllabic constituents: light /l/ occurs as part of an onset and dark /l/ as part of a coda. Another case of allophonic distribution that seems to refer to syllabic constituents is German obstruent devoicing, which has been analyzed as occurring when the obstruent is in coda position (Vennemann, 1978). However, some researchers (Blevins, 2003) have contended that such cases of allophonic distribution are better understood by position within the phonetic string rather than by invoking syllabic constituents.

Third, two types of external evidence that have been used to motivate syllabic constituents are evidence from speech errors (i.e., slips of the tongue) and language games. Speech errors often involve the movement of a phoneme or the exchange of phonemes or sequences of phonemes. Given this indication, researchers such as Shattuck-Hufnagel (1983), Laubstein (1987), and Davis (1988) have pointed out that the speech error evidence from English can be used to support the onset, nucleus, and coda as syllabic constituents. Among the common transposition errors (cited by Davis, 1988 and references therein) are ones involving phoneme reversals such as the actual examples 'caught torses' for 'taught courses,' 'bud begs' for 'bed bugs,' and 'stick neff' for 'stiff neck.' In these errors, syllable-initial elements exchange with one another, vowels exchange with one another, and syllable-final elements exchange with one another. Laubstein (1987: 342) concludes, based on her investigation of such naturally occurring speech errors, that they support the division of the syllable into onset, nucleus, and coda, though not the rhyme. She maintains that "the [speech] errors support a root syllable node that is trinary branching, dominating an initial consonant or consonant cluster, a vowel or vowel glide sequence, and a final consonant or consonant cluster." While the speech error evidence for syllabic constituents is suggestive, it is not conclusive given that there are some speech errors that indeed involve the exchange of other subsyllabic elements (such as 'cassy put' for 'pussy cat').

Researchers such as Davis (1988, 1989), Barlow (2001), and Yip (2003) have brought language game data to bear on the issue of syllabic constituents. An underlying assumption is that if a language game requires the movement of phonemes or the insertion of phonemes, it does so in a way that reflects constituent structure. For instance, Davis (1989) contends that Pig Latin, in which the initial consonant sequence moves to the end of the word (e.g., pig → igpey and blast → astbley), provides evidence for the constituency of the onset in English. A caveat with the use of language games as evidence for constituency is that not all users of language games manipulate the language game in the same way. Barlow (2001) shows that some users of English Pig Latin only move the initial consonant of a consonant cluster to the end of the word, and moreover, speakers are quite inconsistent in their treatment of the coronal onglide in words like 'cute.' Thus, evidence from language games on their own may be inconclusive on specific issues of syllabic constituency.

Finally, a type of evidence that has played an important role in the discussion of syllabic constituency comes from processes that are sensitive to syllabic weight, such as the assignment of stress. Many languages divide syllables into two types according to syllabic weight: light syllables and heavy syllables. Heavy syllables are typically those that have a long vowel or a syllable-final consonant. A light syllable typically ends in a short vowel. Stress is then attracted onto some heavy syllable. In Latin, stress falls on a penultimate syllable if it is heavy, otherwise on the antepenultimate. This proof seems to support the rhyme as a constituent of the syllable, since a heavy syllable would be one that has more than a single element in the rhyme. Detailed examination of the typology of stress (Hayes, 1995), however, shows that in some languages only a long vowel makes a syllable heavy and not a coda consonant. This proof is somewhat problematic for the onset-rhyme division of the syllable, since not all heavy rhymes are treated alike. Instead, such phenomena have been used to motivate the moraic view of the syllable (Hayes, 1989) that abandons onset-rhyme division. On this view, the mora is considered a unit of syllable weight, such that a short vowel forms a single mora, a long vowel constitutes two morae, and a coda consonant may or may not be moraic depending on whether they make a syllable heavy. In Latin, thus, stress falls on the penultimate syllable if it contains a long vowel or if it ends in a consonant, that is, if it is bimoraic; otherwise, stress falls on the antepenultimate syllable. Within the moraic view of the syllable, the issue of the constituency of the onset is an independent matter. While

Davis (1990) argues that syllable-initial consonants can still comprise a constituent within the syllable, most advocates of the moraic approach (McCarthy and Prince, 1995) assume that the syllable initial consonants are adjoined to the syllable and do not form an independent constituent on their own.

One of the reasons that the issue of syllabic constituency has remained controversial is that detailed examinations of individual languages often point to inconsistencies. Ideally, in a single language, a variety of weight sensitive processes which, in addition to stress may include compensatory lengthening, reduplication, and aspects of tonal phonology, will treat all syllables with coda consonants alike, either as bimoraic or monomoraic. However, researchers such as Hyman (1992) have noted moraic mismatches whereby one weight-sensitive process in a language treats a CVC syllable as bimoraic but a different weight-sensitive process treats that same syllable as monomoraic. In this connection, Yip (2003) has provided a variety of examples where in a single language the same prenuclear glide may be treated as an onset element or a nucleus element depending on the speaker and the process involved. Such phenomena have led to suggestions that syllable structure is process specific, as in Vennemann (1988). A formal analysis of this view can be developed within optimality theory (Rosenthall, 1997 and Rosenthall and van der Hulst, 1999) where the realization of moraic elements is contextually dependent.

Syllable: Phonology

T A Hall, Indiana University, Bloomington, IN, USA

© 2006 Elsevier Ltd. All rights reserved.

The syllable is sometimes defined as an uninterrupted unit of the spoken language, which typically consists of a vowel sound flanked by one or more consonants. For example, *mad* [.mæd.] is an example of a word consisting of one syllable, and *basic* [.beɪ.sɪk.] of a word consisting of two. (Note that the dots in the phonetic transcriptions indicate the breaks between syllables.) The presence of consonants flanking the vowel is not a precondition on well-formed syllables, because a syllable can consist of a vowel only, e.g., *I* [.aɪ.]. In many languages it is possible to have syllables built around a consonant and not a vowel, e.g., the second syllable in *able* [.eɪ.bl̩.], in which [l̩] has the same function as a vowel. (The [l̩] here is an example of a syllabic consonant – indicated with the diacritic under the [l]). This article discusses the role of the syllable in phonology.

Phonological Representations

The English word *grand* [.gɹænd.] has at first approximation the following phonological representation. Here and below 'σ' refers to the syllable.

(1)

The representation in (1) consists of five segments, which are simply abbreviations for the corresponding feature matrices Considerable work in phonology has shown that the syllable in (1) is made up of smaller units, e.g., onset, nucleus, coda, and rhyme (*see* **Syllabic Constituents**). A typical representation along these lines for the word *grand* is depicted in (2):

(2)

(3)

It is usually assumed in the literature that the syllable is universal in the sense that all languages have them. A further assumption is that the syllable occupies a fixed position in the universal prosodic hierarchy (see (3); Booij, 1983, Nespor and Vogel, 1986); thus, the constituent 'σ' is dominated by the foot (F), which in turn is dominated by the phonological word (ω). The latter constituent is situated under the phonological phrase (PPh).

Evidence for the Syllable

The reason the syllable is an indispensible unit in phonology is that many phonological generalizations can only be made insightfully by referring to it and not to other units. For example, phonological rules must often refer to syllable boundaries. A typical example is the rule in German and Dutch known as final devoicing, which applies to all obstruents:

(4) $[-\text{sonorant}] \rightarrow [-\text{voice}] \ / \ _]_{\sigma}$

In the formalization in (4) '$]_{\sigma}$' refers to the right edge of a syllable. The effects of this rule can be observed in German examples like *Tag* [.taːk.] 'day' vs. *Tag-e* [.taː.gə.] 'day + plural'. In the singular the underlying /g/ devoices to [k] because it is syllable-final and in the plural the /g/ surfaces as [g] because it is syllable-initial. The reason the rule in (4) cannot be stated so that it applies at the end of a word is because its effects can also be seen word-internally. For example, the [g] in the English word *rugby* surfaces in German as [k] (i.e., German [ʀakbi]) because this segment is syllable-final in German before a consonant. An analysis of the rule in (4) without syllables would be disadvantageous because it would be forced to treat the environments 'at the end of a word' and 'before a consonant' as a disjunction, i.e., /____{#, C}. Such disjunctions are problematic because a word boundary and a consonant do not form a natural class. It should be noted that the rule in (4) has been argued to apply not at the end of a syllable but within a subsyllabic constituent like the coda (recall (2); see Vennemann, 1978; Hall, 1993 for discussion).

Other phonological properties that take the syllable as the domain are stress and tone. For example, in Latin a trisyllabic word is stressed by the following rule: The penultimate syllable is stressed if it is heavy (i.e., consists of a branching rhyme); if the penult is light (i.e., the rhyme is not branching) then the antepenultimate syllable is stressed. Note that a reformulation of the Latin stress rule would be awkward if no reference to the syllable were made.

A similar argument for the syllable comes from phonotactics. For example, in English no word begins with [mɹ] and no word ends with [tm]. These phonotactic constraints for English refer to syllable edges and not to word edges because only the former can capture nonoccurring word-internal sequences, e.g., [tmɹ]. The reason there are no English words like [ɑtmɹə] is that the [tmɹ] sequence cannot be parsed without violating the phonotactic constraints mentioned earlier. Thus, the parsing [.ɑt.mɹə.] would have [mɹ] in syllable-initial position and the parsing [.ɑtm.ɹə.] would have [tm] in syllable-final position. Note too that [tm] and [mɹ] are well-formed sequences when a syllable break falls between the two segments, e.g., [mɹ] in *emerald* and [tm] in *utmost*.

Although the role of the syllable as a phonological unit was denied in Chomsky and Halle (1968), a number of researchers both before and after recognized its importance (e.g., Pike and Pike, 1947; Haugen, 1956; Fudge, 1969; Vennemann 1978).

Sonority

An important principle regarding phonotactics is based on the notion of sonority, where the sonority of a segment is defined roughly as its loudness relative to other sounds produced with the same length, stress, and pitch (see Ladefoged, 1993). An example of a sonority hierarchy (from Clements, 1990) is presented in (5):

(5) Sonority hierarchy ('>' = 'more sonorous than'):
vowels > glides > liquids > nasals > obstruents

In the hierarchy in (5) vowels are the most sonorous segments followed in descending order by glides, liquids (rhotics and laterals), nasals, and obstruents. Many linguists have observed that the segment occupying the nucleus in (2) (also called the peak) is the most sonorous element in the syllable, whereas the onset tends to increase the sonority inwards toward the nucleus, and the coda tends to decrease in sonority away from the nucleus. These tendencies are captured in the following principle (from Selkirk, 1984 and much earlier work, e.g., Sievers, 1901; Jespersen, 1904; Vennemann 1978; Hooper, 1976):

(6) Sonority Sequencing Generalization (SSG):
In any syllable, there is a segment constituting a sonority peak that is preceded and/or followed by a sequence of segments with progressively decreasing sonority values.

The SSG is illustrated with the English word *grand* in (7):

(7)

By contrast, a syllable such as [.ɹgænd.] is not well formed in English because the sonority profile of an initial [ɹg] sequence is not in line with the SSG:

(8)

One of the difficulties with the SSG is that it does not permit words like *axe* [.æks.], because it requires that there should be a descending sonority slope in the coda. (In this example the syllable ends in a sequence of two obstruents, which are equally sonorous). Many languages allow for syllables that display even more dramatic SSG violations, e.g., Russian [.rta.] 'mouth (gen.sg.)', Polish [.te.atr.] 'theater'. Some researchers have argued that the SSG holds exceptionlessly in English (and in languages like Russian and Polish) and that in words like *axe* the final segment is extraprosodic (or extrametrical, or extrasyllabic). In terms of phonological representations, an extraprosodic segment is one that is not associated with the syllable. The general idea of extraprosodicity originally arose in the context of stress assignment, where it was argued that simpler rules of stress assignment could be stated if initial and/or final syllables/segments are ignored (*see* **Metrical Phonology** and **Word Stress**). Extraprosodicity has also been argued to hold for English in initial position in words like *stop*, in which the initial [st] cluster appears to violate the SSG. Thus, according to this view the [s] in *stop* is extraprosodic, and there is no SSG violation. The literature on extraprosodicity is vast; the reader is referred to Hall (2002) for discussion and for arguments against the kind of extraprosodicity described earlier. Other researchers have argued that [s] + stop sequences in words like *stop* are not sequences of two separate sounds, but instead that they consist of two articulations attached to a single X slot on the skeletal tier. Thus, on this view [s] plus stop sequences are examples of complex segments (*see* **Complex Segments**), and therefore a word like *stop* would not violate the SSG.

The Sonority Hierarchy in (5) makes reference to five categories of sounds. A number of studies have argued that it should make finer grained distinctions as well. For example, it is often assumed that

fricatives are more sonorous than stops, that rhotics like /r/ are more sonorous than laterals like /l/ and that high vowels are more sonorous than low vowels. It is often assumed that the Sonority Hierarchy is universal, but many researchers have proposed language-specific hierarchies. The question of what segment types are present in the Sonority Hierarchy is clearly related to how the term *sonority* is defined. See Hooper (1976), Selkirk (1984), Vennemann (1988), Clements (1990), and Ladefoged (1993) for various proposals.

Syllable Typology and Markedness

Many linguists have observed that certain syllable types are more common in the world's languages than others. For example, if we consider the four syllables V, CV, CVC, and VC, there are only four attested language types, as illustrated in (9) (see Blevins, 1995):

(9)

	V	CV	CVC	VC
Hua	no	yes	no	no
Maori	yes	yes	no	no
Klamath	no	yes	yes	no
English	yes	yes	yes	yes

This table reveals that there are some languages like Hua, which only have one syllable type, namely CV, whereas other languages like English allow for all four. Despite the variation among languages, it is possible to make the generalization that all languages have CV syllables (Jakobson, 1962). CV is therefore considered to be the least marked syllable (*see* **Markedness**).

A number of important cross-linguistic generalizations can also be made about syllables with complex onsets and/or codas. For example, if clusters of n Cs are possible in onset position (where $n \geq 2$), then n-1 C or Cs are also possible in onset position. A similar statement can be made for codas: if n Cs are possible in coda position (where $n \geq 1$), then n-1 C or Cs are also possible in the same context (see Greenberg, 1978). Similar kinds of generalizations can be made concerning the sonority of segments in syllable margins. For example, if a language allows complex onsets of the form liquid + obstruent, then the same language will allow onsets of the form obstruent + liquid, e.g., Russian [.rta.] 'mouth, gen. sg.', [.tri.] 'three'.

Cross-linguistic markedness generalizations can also be made concerning the syllable peak (Blevins, 1995). For example, vowels are the least marked peak, whereas consonants are more marked in this position. Thus, there are languages like Bulgarian in which all syllable peaks are vowels, and languages like English in which both vowels and consonants can serve as peaks, but no language restricts syllable peaks only to consonants. Among the vowels, low vowels like [a] make better peaks than high vowels like [i]. Among the consonantal peaks, liquids are less marked than nasals and nasals are less marked than obstruents, the rarest of all syllable peaks, e.g., Imdlawn Tashlhiyt Berber [tf̩tx̩t] 'you sprained' (see Dell and Elmedlaoui, 1985).

Syllabification

Most researchers assume that phonological representations with syllables as in (1) and (2) are not present in the underlying representations and that syllable structure is assigned in the course of the derivation. The main reason for this assumption is that the syllable is predictable. Evidence for the predictability of syllabification is that minimal pairs involving contrastive syllabification (e.g., V.CV vs. VC.V) are absent altogether in most – if not all – languages. Although exceptions to this generalization have been argued to exist (e.g., in Arrernte, see Breen and Pensalfini, 1999), it nevertheless remains true that in the vast majority of natural languages syllabification constrasts like the one described earlier do not exist.

One question that has been discussed in the literature on syllables is the formal mechanism by which syllable structure is assigned to segments within words (see Kenstowicz, 1994 and Rubach, 1999 for current surveys). The basic division among such syllable structure algorithms is between ones in which syllables are assigned by rule (Kahn, 1976) and by template matching (Ito, 1989). According to the latter approach a sequence of segments is scanned in a particular direction from one word edge (i.e., from right to left or from left to right), and successive segments are assigned to slots in a syllable template. To illustrate the right-to-left mapping of a syllable template consisiting of an onset and a rhyme, consider a word like *zebra* /ziːbɹə/. First, the template matches onto the syllable /bɹə/, and then onto the syllable /ziː/. Rule-based approaches posit a set of rules having a similar formal status to other phonological rules, which associate syllable constituents with segments. On this approach the example /ziːbɹə/ is syllabified in the following way: first, two separate rhyme positions are associated with the /iː/ and /ə/, respectively, after which /z/ and /bɹ/ are associated with two separate onset nodes. Note that in both approaches onsets are maximized. For example, the sequence /ziːbɹə/ is syllabified [.ziːbɹə.] in a language like English (and not [.ziːbɹə.]) because [bɹ] is a permissible onset; however, a word like *party* /pɑɹti/ will be parsed [.paɹ.ti.] and not [.pa.ɹti.] because the

sequence [ɹt] cannot surface as an onset due to the SSG violation. It should be noted that syllabification in Optimality Theory (Prince and Smolensky, 1993) is analyzed instead as the interaction of various universal constraints (*see* **Syntax: Optimality Theory**).

Ambisyllabicity

The discussion in syllabification implies that VCV is parsed universally as V.CV, but a number of researchers have argued that the intervocalic C in this context can be ambisyllabic, i.e., it belongs to two syllables. The representation in (10) depicts an ambisyllabic consonant:

(10)

Linguists who have argued for ambisyllabic consonants include Kahn (1976) and Rubach (1996) for English, Clements and Keyser (1983) for Efik, and Wiese (1996) for German.

Kahn (1976) argues that the rules governing the distribution of the allophones of /p t k/ in American English require reference to ambisyllabic structures. Thus, in his treatment, /p t k/ surface as aspirated in absolute syllable-initial position, but /t d/ surface as flapped when ambisyllabic, e.g., the /t/ in *city* ([sɪɾi]). In German it is often assumed that lax vowels like [ɪ] never occur in syllable-final position (e.g., Wiese 1996). If this is the correct environment, then it suggests that the /t/ in a word like *Bitte* [bɪtə] 'request' is syllable-final. However, the same /t/ is aspirated, which is typical of syllable-initial voiceless stops. The solution to this apparent paradox (which is adopted by Wiese 1996 among others) is that the segment in question is ambisyllabic, as in (10).

It needs to be emphasized that ambisyllabic structures in phonology are controversial. For example, Kiparsky (1979) and Jensen (2000) argue that the rule of flapping in American English referred to earlier applies not to ambisyllabic /t d/, but instead to /t d/, which are internal to a foot (*see* **Metrical Phonology**).

Conclusion

In this article it has been demonstrated that the syllable is an important unit in phonology. The article presented phonological arguments for the syllable and showed that the notion of sonority is essential for an understanding of phonotactic patterns. Generalizations concerning the types of syllables found in the languages of the world and the way in which languages syllabify sequences of sounds within words were discussed. The article concluded with a brief discussion of ambisyllabicity.

Syllable: Typology

J Blevins, Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany

© 2006 Elsevier Ltd. All rights reserved.

In many languages, there is substantial evidence that speech sounds are organized into syllables. In slow speech, words may be uttered syllable by syllable, and the syllabic position of segments and features tends to remain constant in speech errors. In speech disguise and language play, syllables are manipulated, and a range of sound patterns requires reference to the syllable as domain, to syllable edges, or to subsyllabic constituents (Blevins, 1995).

This article reviews the range of syllable types in the world's languages in relation to sound patterns or properties typically associated with syllables. These include sonority, general phonotactics, feature-based phonotactics, and weight. The purpose of this article is to demonstrate the extent to which syllable types vary crosslinguistically, and to highlight crosslinguistic generalizations. In each case, exceptions to universal tendencies are noted, as are languages with sound patterns at the typological extremes.

The following discussion makes use of some standard terms that are applied to the description of syllables. The 'nucleus' or 'peak' refers to the syllabic element or elements within the syllable and contains the sonority peak; the term 'onset' refers to elements preceding the nucleus, and 'coda' to elements following the nucleus. The term 'rime' refers to a constituent made up of the nucleus and coda. The symbol C denotes a nonsyllabic segment, V a syllabic segment, R a sonorant consonant and T an obstruent consonant.

Sonority

The syllable is often thought of as a unit that organizes speech sounds in terms of their intrinsic sonority. A rough definition of sonority is the loudness of a sound relative to the energy used to produce that sound. Vowels are highly sonorous sounds, while voiceless stops have low sonority. Most phonologists and phoneticians agree on a sonority scale in which low vowels are the most sonorous segments, followed in decreasing sonority by mid vowels, high vowels, high glides, liquids, nasal stops, fricatives, and oral stops. Sonority is often claimed to play a role both in the overall contour of syllables, and in the range of segments which can serve as syllable peaks or nuclei.

At the level of overall syllable sonority profiles, there is a strong tendency for syllables to rise in sonority or remain steady up to the sonority peak, and to remain steady or fall in sonority thereafter. This tendency is sometimes referred to as the Sonority Sequencing Generalization (SSG) or the sonority sequencing principle. Hawaiian, a language with only open syllables, obeys the SSG, since there is always a sonority rise from the nonsyllabic onset to the syllabic nucleus. Within the nucleus, sonority may remain steady or fall. In Yawelmani, where any single consonant may occur as onset or coda, there are also no exceptions to the SSG. A crosslinguistic generalization that emerges is that the SSG is obeyed in all languages which allow only a single consonant to precede and/or follow the syllable nucleus. Examples of languages supporting this generalization are given in **Table 1**. (In all tables, nongenetic language groups are given in parentheses in the 'Family' column.)

In languages where syllables may begin or end in a consonant cluster, adherence to the SSG is less

In many languages, there is substantial evidence that speech sounds are organized into syllables. In slow speech, words may be uttered syllable by syllable, and the syllabic position of segments and features tends to remain constant in speech errors. In speech disguise and language play, syllables are manipulated, and a range of sound patterns requires reference to the syllable as domain, to syllable edges, or to subsyllabic constituents (Blevins, 1995).

This article reviews the range of syllable types in the world's languages in relation to sound patterns or properties typically associated with syllables. These include sonority, general phonotactics, feature-based phonotactics, and weight. The purpose of this article is to demonstrate the extent to which syllable types vary crosslinguistically, and to highlight crosslinguistic generalizations. In each case, exceptions to universal tendencies are noted, as are languages with sound patterns at the typological extremes.

The following discussion makes use of some standard terms that are applied to the description of syllables. The 'nucleus' or 'peak' refers to the syllabic element or elements within the syllable and contains the sonority peak; the term 'onset' refers to elements preceding the nucleus, and 'coda' to elements following the nucleus. The term 'rime' refers to a constituent made up of the nucleus and coda. The symbol C denotes a nonsyllabic segment, V a syllabic segment, R a sonorant consonant and T an obstruent consonant.

Sonority

The syllable is often thought of as a unit that organizes speech sounds in terms of their intrinsic sonority. A rough definition of sonority is the loudness of a sound relative to the energy used to produce that sound. Vowels are highly sonorous sounds, while voiceless stops have low sonority. Most phonologists and phoneticians agree on a sonority scale in which low vowels are the most sonorous segments, followed in decreasing sonority by mid vowels, high vowels, high glides, liquids, nasal stops, fricatives, and oral stops. Sonority is often claimed to play a role both in the overall contour of syllables, and in the range of segments which can serve as syllable peaks or nuclei.

At the level of overall syllable sonority profiles, there is a strong tendency for syllables to rise in sonority or remain steady up to the sonority peak, and to remain steady or fall in sonority thereafter. This tendency is sometimes referred to as the Sonority Sequencing Generalization (SSG) or the sonority sequencing principle. Hawaiian, a language with only open syllables, obeys the SSG, since there is always a sonority rise from the nonsyllabic onset to the syllabic nucleus. Within the nucleus, sonority may remain steady or fall. In Yawelmani, where any single consonant may occur as onset or coda, there are also no exceptions to the SSG. A crosslinguistic generalization that emerges is that the SSG is obeyed in all languages which allow only a single consonant to precede and/or follow the syllable nucleus. Examples of languages supporting this generalization are given in Table 1. (In all tables, nongenetic language groups are given in parentheses in the 'Family' column.)

In languages where syllables may begin or end in a consonant cluster, adherence to the SSG is less

Table 1 Sonority sequencing generalization: obeyed in all languages with simple onsets and simple codas

	Language/Data source	*Family*	*Sample syllable types*	
(C)V(V)	Bilua Obata (2003)	(Papuan)	i.nai.nae.ko	'to prepare'
(C)V(V)(V)	Banawà[a] Buller *et al.* (1993)	Arawan	u.fa.bu.ne	'I drink'
			ba.due	'deer sp.'
			buei	'die'
(C)V(V)	Hawaiian[b]	Austronesian/Polynesian	a.lo.ha	'love'
	Pukui & Elbert (1971)		ōō.pū.he.a	'quiet, calm'
(C)VʔV	Tarahumara[c]	Uto-Aztecan/	a.ká	'sandal'
	Lionnet (1972)	Sonoran	uʔ.sú	'grandmother'
CV(X)	Yawelmani[d]	Yokuts	mt.jt.net.naʔ	'I was made tired'
	Newman (1944)			
CV(V)(C)	Karuk (Karok)[e]	(Hokan)	ʔa.ra:r	'person'
	Bright (1957)		fi:.pa.jav	'straight'
(C)V(X)	Lele[f]	Afro-Asiatic/	ŋ.lèé.sì.kaŋ.di	'I ate meat here'
	Frajzyngier (2001)	Chadic	am.du	'he kept her'
			túg.sú	'k.o. grass'
			è, éè	'go,' 'go-FUT'
(C)V(V)(C)	Yupik Jacobsen (1984)	Eskimo-Aleut/Eskimo	a.cu.raq	'aunt by marriage'
			aa.luu.yaaq	'swing'
			uug.nar	'vole'

[a]Onsetless syllables are all of the form V, with simple nuclei. CVVV syllables only occur word-finally, and the final vowel is always /i/. Buller *et al.* (1993) interpret word-initial Vs and word-final /i/ of VVi as extraprosodic segments.

[b]Tautosyllabic VV sequences in Hawaiian include all long vowels, possibly clusters of falling sonority, e.g., /ai/, /au/, /ae/, /ao/, etc., and /iu/. Long vowels are written with macrons. By some analyses (e.g., Schütz, 1981), some V_1V_2 clusters where V_1 is long and V_2 is short may also be tautosyllabic: e.g. *āāina* 'land.'

[c]Vowels in Tarahumara may be checked by glottal closure or unchecked. It is unclear whether to treat this glottalization as a vowel feature, or as an independent coda consonant. Within the word, there is morphologically conditioned reduction of certain vowels to schwa or zero. Recent loans into Tarahumara have word-initial clusters and final consonants, but the SSG is still observed.

[d]Yawelmani has CV:C syllables in a limited number of contexts: where the verbal *-lsa:, -sa:* causative/repetitive suffix is involved, e.g., in *nine:lsa:hin* 'get (him) to keep still several times' (cf., *nini:-* 'keep still'); in *-wiyi-/witi-* verbs indicating extended events, e.g., *pa:lwiyi-* 'overspread slowly' (cf., *palwiyi-* 'overspread quickly'); and in loans, e.g., *gaxt:n* 'box.'

[e]Unstressed phrase-initial ʔV is optionally elided in Karuk, resulting in phrase-initial clusters. Compare phrase-initial *kva:t* or *ʔakva:t* for /akva:t/ 'raccoon.'

[f]Lele has a single syllabic consonant *ŋ* 'I' which occurs as an independent V syllable, without onset or coda. Lele also has productive closed syllable shortening, by which /(C)V:C/ surfaces as (C) VC. Long vowels are written as doubled letters.

regular, as illustrated in Table 2. In Cheke Holo, with only open syllables, we find syllable types V, CV, and TRV and strict adherence to the SSG. However, in Leti, with maximal CCV:C syllables, initial RT clusters violate the SSG. Similar splits are found for languages with complex codas: in both Ndjébbana (Djeebbana) and Yir Yoront, maximal syllables are CVCC, but in the former, complex codas are limited to RT, while in the latter, word-final TR sequences are also found.

Well-studied Indo-European languages which violate the SSG include Russian and Czech, with word-initial RT clusters, and Romanian, with word-final TR clusters. Extreme violations of the SSG occur in Georgian, a Kartvelian language, where word-initial tautosyllabic prevocalic clusters include /zrd/, /mkrt/, /msχv/, and /mcvrtn/. Violations of the SSG in these and many other languages have inspired numerous strategies for maintaining strong versions of the SSG in which the offending consonants are treated as headless or degenerate syllables (which do not count for weight, stress, or tone); as segments prosodically licensed by the foot, word, or phrase; or as unsyllabified morae. For details of these and other strategies, see papers in Féry and van de Vijver (2003) and the comprehensive treatment of syllable appendices in Vaux (2004).

Interestingly, however, there is little evidence from psycholinguistic experiments or native speaker intuitions that suggests that these cases are anything other than true violations of the SSG. Whatever the status of these surface violations of the SSG, one clear generalization which emerges from crosslinguistic surveys is that exceptions to the SSG are found only in languages which allow consonant sequences to precede or follow the syllable nucleus. There do not appear to be any languages in which a complex nucleus itself violates the SSG (e.g., no instances of monosyllabic /aia/, /aua/, etc.), or in which a CV or VC sequence violates the SSG where V is a syllabic segment and C a nonsyllabic segment.

Table 2 Variable adherence to sonority sequencing generalization in languages with complex onsets or complex codas

	Language/Data source	*Obeys SSG?*	*Family*	*Sample syllable types*	
$(C_1^2)V(V)$	Cheke Holo[a] White *et al.* (1988)	yes	Austronesian/Western Oceanic	e.lo	'to float'
				kai.ka.fli	'flash on & off'
				kmai.kma.ji	'eat a varied meal-RED' (RED = reduplication)
$(C_1^2)V(V)(C)$	Leti van Engelenhoven (1995)	no	Austronesian/Central-Malayo-Polynesian	o.a	'you'
				pni.nu	'fool'
				rka:.lu	'they shout'
				sra:t	'main road'
				rstp.le	'they sail'
$(C)V(C_1^2)$	Ndjébbana[b] McKay (2000)	yes	(Australian/Non-Pama-Nyungan)	n.ka.la	'fork'
				ran.ba	'beach'
				kalk.bet	'northern black wallaroo'
$(C)V(C_1^2)$	Yir Yoront[c] Alpher (1991)	no	Pama-Nyungan	pam, am	'person'
				ŋo.jo, o.jo	'I'
				melt	'animal, bird'
				patl	'clean, bald'

[a]Syllable-initial CC clusters in Cheke Holo (a.k.a. Maringe) are TR, where T is an obstruent and R a sonorant. The only other CC clusters which occur in the native vocabulary are word-medial nonhomorganic NN clusters, e.g., *emno* 'be limp'. These are assumed to be tautosyllabic, based on the syllabification of other clusters. Closed syllables do occur loans from Pidgin, as in e.g., *devol, fren, kikibol, wenesde*.

[b]In addition to the syllabic nasal, which forms a V syllable of its own in Ndjébbana, there is one vowel-initial word reported: *a.rab.ba* 'and, but,' a variant of the more common *ka.rab.ba*.

[c]It is inclear whether VCV in Yir Yoront is consistently syllabified as V.CV or VC.V. Dropping of initial consonants in Yir Yoront is typical with pronouns and other particles postconsonantally, and in phrase-initial positions. Otherwise, word-initial vowels are not found. Final CR clusters are distinct from final CvR sequences, where 'v' = schwa. See Alpher (1991: 14–15) for further discussion.

Sonority is also assumed to play a role in defining segments which can serve as syllable nuclei. In many languages, including all the languages in Table 1 with the exception of Lele, syllable peaks are limited to vowels. In other languages such as Lele in Table 1 and Ndjébbana in Table 2, syllable nuclei include vowels and nasal consonants. In modern American English, syllable nuclei include vowels, liquids, and nasals, while an extreme case of consonant syllabicity is described for Imdlawn Tashlhiyt Berber (Tachelhit) (Dell and Elmedlaoui, 1985), where any vowel or consonant, including voiceless stops, can serve as a syllable nucleus in the appropriate segmental context.

In general, if a segment with a relatively low sonority value can serve as a syllabic nucleus in a language, then any segment of greater sonority can also serve as a syllabic nucleus. However, languages like Lele and Ndjébbana, which have syllabic nasals but not syllabic liquids, are well represented crosslinguistically and such systems, as exemplified within Bantu, appear to be quite stable. If evidence comes to light that syllabic liquids are systematically excluded in languages of this type, then the universal role of the sonority scale in defining possible syllable peaks will have to be reevaluated.

Sonority has also been taken to play a role in limiting single-member onsets to low-sonority segments, and single-member codas to high-sonority segments. However, there is ultimately no secure empirical basis for such generalizations (Blevins, 2004). No language limits onsets to obstruents, nor does any known language ban all sonorants from onset position. Although there are some languages in which single codas are limited to particular sonorants, these patterns do not cover contiguous ranges on the sonority scale. For example, in Manam, an Oceanic language, where only nasals are possible codas, liquids /l/ and /r/ must be prohibited from coda position, which raises problems for a sonority-based account. See Blevins (2004), where convergent evolution is shown to account for the preponderance of nasal codas in the world's languages.

General Phonotactics

A variety of general constraints on the form of syllables has been proposed, including: the requirement that syllables must have onsets; a prohibition against syllables with codas; and constraints against consonant clusters within the syllable. These three constraints are claimed to encode three corresponding crosslinguistic tendencies: the preference for syllables with onsets over those without; the preference for open syllables over closed ones; and the preference for syllables with simple consonantal onsets or codas over those with clusters in the same positions. As with proposed

sonority constraints on single-member onsets and codas, the empirical basis for such generalizations is somewhat weak.

Though many have claimed that CV syllables are the least marked syllable type, few if any of the world's languages have only CV syllables, where C is a single nonsyllabic segment, and V is a (short) syllabic segment. As shown in Table 1, languages with only open syllables typically have optional onsets. In addition, most of these languages allow long vowels, diphthongs, or checked vowels, which can be analyzed as complex nuclei. The rarity of CV-only languages forces one to question the association between syllable typology and proposed markedness constraints.

In many of the world's languages, words begin with vowels, with no evidence of an onset requirement. And in a few rare cases (e.g., Eastern Arrernte), even medial VCV sequences appear to defy the onset constraint, being syllabified as VC.V (Breen and Pensalfini, 1999). Rules of consonant epenthesis do not appear motivated by the onset constraint (Blevins, forthcoming). And the claim that such tendencies are emergent under reduplication is also difficult to reconcile with patterns like those found in Cheke Holo and other languages of the Solomon Islands, where base-initial (C)VCV strings are reduplicated as (C)V.V strings with medial onsetless syllables (Blevins, 2003).

At the same time, there are many languages where words freely end in consonants, with no evidence of an open-syllable preference. In at least two different language families, there is evidence of a preference for closed, not open syllables. In Olgol/Oykangand, a Paman language of Cape York, there are no open syllables in the native vocabulary. In several different subgroups of Austro-Asiatic, all words end in consonants. This was true of Dvaravati Old Mon, and holds for the modern Palaungic, Khmuic, and Aslian branches, where final open syllables do not exist except in borrowings. Again, the claim that a tendency towards open syllables is emergent under reduplication is also difficult to reconcile with patterns like that found in at least one dialect of Southern Oromo (Borana-Arsi-Guji Oromo), a Cushitic language of Kenya, where base-initial CV strings are reduplicated as CV*m*.

The empirical support for constraints against complex onsets and codas appears to be based on languages in which certain clusters are split by epenthetic vowels. However, there appear to be just as many languages in the world which tolerate the same cluster types, as well as languages such as Georgian in which the extremely long clusters noted above are tolerated without epenthesis. Hence, it is incumbent on proponents of constraints against complex onsets or codas to argue that these constraints are not language specific, as they in fact appear to be.

The preference for V or CV syllables does characterize early stages of language acquisition, a point that has sometimes been taken to support a preference for open syllables and a dispreference for clusters in the grammar. However, it is widely accepted that such early patterns reflect production difficulties in coordinating distinct consonantal gestures, and have no ultimate effect on the form of the adult grammar.

Feature-Specific Phonotactics

The distribution of laryngeal and place features is also claimed to be sensitive to syllable structure. For instance, numerous languages show neutralization of obstruent voicing or place contrasts in word-final and preconsonantal position. In many cases, this type of sound pattern can be captured with reference to syllable-final position, or neutralization within the syllable coda. However, recent work on word-based phonotactics also draws attention to the numerous languages where neutralization is not syllable based (Steriade, 1999a, 1999b). A prime example is the common neutralization of retroflex and nonretroflex coronals, which occurs in word-initial and postconsonantal positions, but not in postvocalic positions. Since postvocalic contexts include V.CV as well as VC.C and VC##, a purely syllable-based generalization is not possible.

While it is often the case that the class of possible syllable codas is more restricted than the class of syllable onsets, this is not always the case. In Kashaya, glottalized sonorants only occur in coda position, making the class of possible codas larger than the class of possible onsets.

Weight

Many languages distinguish between 'light' and 'heavy' syllables for the purposes of stress patterns, tone patterns, or metrical traditions. The most common divisions of syllable weight involve only the syllable rhyme and ignore the syllable onset. Of these, the most common divisions for stress are those in which VV is heavy and V is light, or where VV and VC are heavy and V is light. For tone, where heavy syllables are those with two (or more) tone-bearing units, the situation is slightly different. The most common division is one where VV is heavy and V is light, or where VV and VR are heavy, and V and VT are light (R a sonorant, T an obstruent).

No language appears to have more than a three-way contrast in rime weight for the purposes of stress.

A language that exhibits the maximal three-way contrast is Klamath (Klamath-Modoc), where syllables with long vowels are heaviest, followed by closed syllables, followed by light open syllables. On the other hand, there are languages such as Cayuvava (Cayubaba), where no long vowels, diphthongs, or closed syllables occur, and which have only a single 'light' syllable type.

A few languages are described in which syllable weight is sensitive to syllable onset. One language of this type is Pirahã (Múra-Pirahã), where the heaviest syllables are TVV (where T is a voiceless obstruent), and these are heavier than DVV (where D is a voiced consonant), which are in turn heavier than VV syllables without onsets. The complete six-degree weight scale is TVV > DVV > VV > TV > DV > V, and represents one of the most complex scales described for a stress system (Everett and Everett, 1984).

In languages in which morae and not syllables are the stress- or tone-bearing units, there appears to be no upper limit on the number of morae within a syllable. Although many languages have an upper limit of two morae per syllable, trimoraic syllables are also found in many unrelated languages, including Japanese, Estonian, and Hawaiian. Gilbertese (Kiribati) *raoim* 'your tranquillity' has four morae, and nothing in Gilbertese rules out the unattested five-mora syllable /a:oim/.

Recent work on syllable weight (Gordon, 2002, 2004) demonstrates that the most common weight systems for tone and stress are grounded in phonetic properties relevant to the realization of these features. For stress, overall acoustic energy is relevant, while tone systems are characterized by high-sonority weight units capable of carrying fundamental frequency contours with some degree of perceptual salience. These findings are consistent with the fact that some languages with tone and stress have distinct weight systems. The same facts suggest that the search for a universal unified theory of syllable weight for stress and tone is misguided.

Symbolic Computational Linguistics: Overview

G Penn, University of Toronto, Toronto, ONT, Canada

© 2006 Elsevier Ltd. All rights reserved.

Computational linguistics (CL) refers to a collection of topics that lie at the intersection of linguistics, computer science, mathematics, psychology, philosophy, and/or neurophysiology. The name is applied equally often to research that uses computers or mathematical methods as tools in the course of what is otherwise purely theoretical linguistic investigation, as it is to research on the construction of computational devices that perform useful linguistic tasks. The latter type of research, however, is often referred to more specifically as natural language processing (NLP). CL also formerly included research on applications of computing to traditional humanistic disciplines – as alternatives to or extensions of textual concordances, for example – but this is perhaps more accurately described as literary computing.

'Symbolic' computational linguistics refers to one of three particular perspectives on computational linguistics:

1. The study of language as a symbolic system in the profound sense of this term as it was used in early artificial intelligence research, most notably by Alan Newell and Herbert Simon. In their view, a computer simulation of such a system, which would include some internal representation of meaning, could be said to understand language. Such philosophically strong claims have become increasingly rare in CL, although the term 'natural language understanding' is still applied to natural language processors that pay particular attention to meaning and reasoning.
2. A view of language, normally of human language processing (*see* **Human Language Processing: Symbolic Models**), that can be counterposed with subsymbolic models of language comprehension, of which connectionist models of human language processing are the most common instances. Here, the term, 'symbolic' is used somewhat disparagingly in reference to the unlikelihood of finding physiological manifestations of logical expressions, trees, or other discrete algebraic structures in the brains of human subjects.
3. A diverse body of research devoted to natural language processing in the absence of statistical pattern recognition techniques (*see* **Language Processing: Statistical Methods**). This is a false dichotomy, as a great many statistical methods use the same symbolic representations, either directly annotated with numerical parameters, or through some structure-preserving embedding (called a 'kernel method') into a large-dimensional vector space.

These three perspectives are, of course, related. Symbolic representations of meaning, in the sense of the second perspective, were by far the predominant choice of the symbolic systems of the first perspective. This predominance is often attributed to early work by Marvin Minsky and Seymour Papert that clearly delineated some limitations of perceptron networks, an early form of connectionist model. These same symbolic representations are the very close historical antecedents of those used today in the symbolic CL of the third sense. All of them endeavor to remain faithful to the descriptive devices of prevalent theoretical models from psychology or linguistics, even when those devices can claim no straightforward correspondence to human neurophysiology.

A Road Map of Symbolic CL

Figure 1 depicts an example of the stages in generating a phone string to be spoken from an initial conceptual goal in a typical symbolic NLP system. The diagram is organized according to the different levels of linguistic representation involved in this task, called concept-to-speech synthesis. Nearly all symbolic CL research can be thought of either as an elaboration of the algorithms or representations involved in some aspect of this process (or its reverse, spoken language understanding), or as an investigation into how humans accomplish the same. The honorary exception is research on the structure of writing systems, which has applications to text-to-speech synthesis (*see* **Speech Synthesis**).

We can imagine that an agent begins with a goal that it must satisfy. Planning refers to the construction of a strategy for attaining that goal. CL becomes involved when the agent must communicate with other agents in order to delegate tasks from this strategy or to obtain information that it needs to proceed through it. When human agents are involved, all of the agents must observe a number of conventions for that communication to proceed naturally, some of which must be taken into account during planning (*see* **Speech Acts and Artificial Intelligence Planning Theory**). In addition, in each turn of the dialogue, the agents must use an utterance that adheres to a different but equally important set of conventions that govern the connection between its form and its intended meaning. This latter set of conventions is loosely known as grammar, although it is possible to speak of several grammars in a process as comprehensive as

Figure 1 A schematic of symbolic computational linguistics in the context of concept-to-speech synthesis.

concept-to-speech synthesis. Each grammar then governs a specific connection between two levels of linguistic structure. Syntax, in its most general usage, refers to the study of form in the more superficial of any two such levels as an encoding of some meaning, whereas semantics refers to the study of form in the less superficial level, particularly as it is used to convey the meanings of the more superficial level's forms more directly. In their more specific (and in linguistics, more common) usage, syntax and semantics refer to the two specific levels shown in Figure 1, which stand in exactly this relationship.

After planning comes generation, the production of a string of words for a planned utterance. Generation is typically distinguished into two phases. The first, strategic generation, is essentially an extension of planning into linguistic structure. This is particularly necessary for long utterances or the generation of textual documents rather than speech, in which the information conveyed must be sequentially and coherently organized. The second, tactical generation, or surface realization, actually uses the syntactic rules and lexicon of a grammar to choose words and to place them into a particular order. Most generation systems include a third, intermediate stage, sometimes called microplanning, during which the natural language expressions that refer to entities in the discourse are chosen (*see* **Generating Referring Expressions**), and component phrases are combined into more complex sentences in a process called aggregation. Complex sentence structure, although not appropriate in every circumstance, has proved to be a necessary means of conveying the relative importance of different pieces of information.

The reverse of surface realization, in which a string of words is analyzed into a semantic form, is known as parsing. Some of strategic generation is effectively reversed by discourse segmentation and discourse parsing, in which the overall plan of a document and the roles of its sentences are determined. The reverse of referring expression generation is called reference resolution, an important part of which is

determining the antecedents of certain very context-dependent expressions, such as pronouns (*see* **Anaphora Resolution: Centering Theory Approach**). Although meaning representations are generally designed to be unambiguous, natural language is often ambiguous, even with the best of planning strategies. Ambiguity resolution, which determines which of several possible meanings was intended, therefore forms a very large part of spoken language understanding. Ambiguity resolution, reference resolution, and the various forms of reasoning that are applied to semantic forms in this direction of processing are collectively known as semantic interpretation.

Morphological realization builds words that bear the properties that syntactic structure requires them to have. Among the Indo-European languages, this classically involves attaching suffixes indicating person, number, and gender onto verbs, which must agree with those of their subjects, and case, number, and gender onto adjectives, which must agree with those of the nouns they modify. Prior to realization, these properties are often represented as bundles of abstract feature-value pairs, so this process involves finding the right reflexes of these features (morphophonemic, or, for text generation, morphographemic, correspondence), and the right order in which to combine them (morphotactics; *see* **Morphology and Language Processing**). English has a remarkably simple morphological system, but Finnish and Arabic both have very complicated ones and have had a remarkable impact on computational morphology research.

Once the necessary sequences of morphemes have been realized, phonological realization determines how their pronunciations will change in that context. Pronunciation can change as a result of either word-internal combination with other morphemes, or word-external juxtaposition with other inflected words. To many researchers, the holy grail of computational linguistics is speech-to-speech machine translation, in which spoken input in one language is translated to another language and automatically synthesized by a computer. Among nonstatistical approaches to this task, a common one is to attach a spoken-language-understanding system to a content-to-speech synthesizer at their plan/meaning ends, through a system of transfer rules that account for various mismatches between the two language-specific meaning representations. With certain closely related languages, some researchers attempt to use a common meaning representation for both languages, called an interlingua representation (*see* **Machine Translation: Interlingual Methods**).

There is an overwhelming amount of evidence that humans do not generate their own speech in such a modular, pipelined fashion, and, indeed, suitably efficient NLP systems would not be able to adhere to this view internally either. In English spoken language processing, for example, the relative importance of information can be altered in a sentence either by changing word orders through more complex sentence structures, and/or through the use of special adverbs and conjunctions such as 'basically' and 'although' (*see* **Discourse Markers**), and/or through the use of a different prosodic intonation contour, in which the pitch of the speaker's voice changes. No single linguistic level in Figure 1 mediates all of these factors. Similarly, in some languages, aggregation could not be undertaken without proper consideration of the available derivational morphemes, which alter the parts of speech and meanings of the words to which they attach. The tricks of the trade are nevertheless presented in the literature as departures from the point of view depicted here, largely because the vocabulary we have inherited from linguistic theory for describing these systems implicitly assumes it (*see* **Modularity**).

Manners of Representation

As alluded to in the preceding section, the most lasting contribution of symbolic CL research has been the formal representations of linguistic information that it has proposed. These continue to be used today, even in areas wherein purely nonstatistical methods have long since been abandoned. The representation types proposed can be broadly classified into logical, graphical, and featural. The most salient alternative to using one of these representations is the string. Strings are easy to overlook because they are the first symbolic representation that we learn for language at a very young age, but mathematically, they are one of only two algebraic structures that are associative (xy appended to z is the same as x appended to yz), but not commutative (xy is not the same as yx). The other such algebraic structure is matrix multiplication; the deep structural correspondence between these two algebras has not been utilized nearly as much as it should be.

Strings were the basis for the first probabilistic models applied to linguistic data. These appeared in the realm of automatic speech recognition, whereby knowledge of the relative frequencies of all three-word sequences, called trigrams, can be used to correct recognition errors by an acoustic model. Classically, these probabilistic trigram models were called language models by electrical engineers, although this term can now refer to models that are linguistically much richer than three-word sequences. Strings also played a pivotal role in early generative linguistics. The early work of Noam Chomsky on syntactic structures defined a

system of transformations, i.e., rules that can locally rewrite parts of strings according to their context. Contextualized string rewriting is still a staple of phonological rules. These are equivalent to finite-state transductions (see later, Finite-State Machines) if every transformational rule can apply no more than a bounded number of times to its own output (Johnson, 1972), which is generally the case in phonology.

Another common alternative, particularly in information retrieval, is the 'bag of words' model, in which only the number of each kind of word is retained – not even the order. A bag of words for a document can be represented by a vector in which each dimension corresponds to a word type (either a word, or the class of all words with the same lexical stem), and the value at that dimension is the number of instances of that word type appearing in the document. A common method for comparing the similarity of two documents is to compute the cosine of their corresponding vectors.

Logical

First-order predicate logic (*see* **Frege, Gottlob (1848–1925)**) is the noble ancestor of mathematical logic, and its varision extensions are still the representation of choice among semanticists for the meaning of natural language expressions. Systems that deal with natural language in more restricted domains, however, such as travel reservations, banking transactions, etc., generally use a featural representation.

Propositional Logic The language of propositional logic begins with a collection of propositional variables that represent statements about the world (in a human language, supposedly) that are either true or false. These include statements for which truth value may vary as a function of time or other aspects of context. For example, *Felix is a cat* depends on whether the name 'Felix' refers to a cat or a dog, and *Felix is sitting on a mat* may depend on Felix's position as a function of time. It may even include statements for which we do not know a truth value, provided that it makes sense to assign them one. *Felix is thinking of tuna* has a truth value, for example, even if we do not have access to Felix's thoughts, but a question such as *What is Felix thinking of?* does not have a truth value, regardless of what Felix is thinking of or even whether Felix is thinking. A valuation is a function that assigns a truth value to every propositional variable in our collection, taking all necessary aspects of context into account.

This picture by itself is rather uninteresting, because the valuation is doing all of the work – nothing about the name of a propositional variable tells us whether its corresponding statement is true or false.

Table 1 Natural language constructions and their decompositions in propositional logic[a]

Construction	*Formal expression*
A 'and' *B*	$\phi \wedge \psi$
A 'or' *B*	$\phi \vee \psi$
'if' *A* 'then' *B*	$\phi \rightarrow \psi$
'not' *A*	$\neg\phi$

[a]*A* and *B* are truth-valued statements in natural language; ϕ and ψ are their respective formal expressions in the language of propositional logic.

Rather than associate every statement we might wish to express with a variable, then, the language of propositional logic allows us to decompose some constructions in natural language into a formal combination of one or more variables. Instead of associating a single variable with *Felix is a cat and Felix is sitting on a mat*, for example, we can combine the variable for *Felix is a cat*, p, with the variable for *Felix is sitting on a mat*, q, in the expression, $p \wedge q$. Similarly, *If Felix is a cat, then Felix is thinking of tuna* can be associated with the formal expression, $p \rightarrow r$, where r is the propositional variable for *Felix is thinking of tuna*. There are four natural language constructions that can be so decomposed in propositional logic, as shown in Table 1. What really makes this worthwhile is that we still only need a valuation to interpret these. Propositional logic comes equipped with an automatic means of telling us the truth value of any formal expression formed by any combination of variables and these four connectives, or modes of combination, given just the valuation. This automatic means is reflected in a deductive system, which consists of rules that each guarantee the truth of certain expressions based on the truth of other expressions. To most people, a logic actually refers to the deductive system, not to the language of expressions. Another branch of mathematics, called model theory, studies the algebraic relationships that the automatic means of determining truth induce among the different expressions of the underlying formal language. Of particular importance is Boolean algebra (*see* **Boole, George (1815–1864)**), the algebra that models classical propositional logic (see later). These four connectives – conjunction, disjunction, implication, and negation – are sometimes called Boolean connectives. Despite the advent of propositional logic, semanticists are still gainfully employed because (1) there are far more interesting formal decompositions of natural language than these four connectives and (2) even in the case of these four, our use of them in natural language often results in meanings not predicted by the machinery of propositional logic.

$$\frac{\phi \quad \psi}{\phi \wedge \psi}\ \wedge I \qquad \frac{\phi \wedge \psi}{\phi}\ \wedge E_1 \qquad \frac{\phi \wedge \psi}{\psi}\ \wedge E_2$$

$$\frac{\phi}{\phi \vee \psi}\ \vee I_1 \qquad \frac{\psi}{\phi \vee \psi}\ \vee I_2 \qquad \frac{\phi \vee \psi \quad \phi \rightarrow \chi \quad \psi \rightarrow \chi}{\chi}\ \vee E$$

$$\frac{\begin{array}{c}\overline{\phi}^{u} \\ \vdots \\ \bot\end{array}}{\neg\phi}\ \neg I^{u} \qquad \frac{\neg\phi \quad \phi}{\bot}\ \neg E$$

$$\frac{\begin{array}{c}\overline{\phi}^{u} \\ \vdots \\ \psi\end{array}}{\phi \rightarrow \psi}\ \rightarrow I^{u} \qquad \frac{\phi \rightarrow \psi \quad \phi}{\psi}\ \rightarrow E$$

Figure 2 The inference rules of minimal propositional logic.

Accepting the idealism of propositional logic for the moment, one particular rule of importance in propositional logic's deductive system tells us that, given the truth of $\phi \rightarrow \psi$ and ϕ, we may conclude that ψ is also true. This rule is so important that it has a name, modus ponens. It allows us not only to prove the truth of individual statements, but also to consider a collection of statements, called a theory, and then to think of all of the statements that logically must follow from them. This use of logic has become paramount among mathematicians, its continued relationship with natural language semantics being relegated to a pastime of formal linguistics. Assuming the existence of a constant $\bot$ that represents contradiction, we can describe the deductive system of minimal propositional logic as shown in Figure 2. Modus ponens appears there as $\rightarrow E$. The E-rules are elimination rules that produce a consequent (below the line) from which the connective under examination has been eliminated. The I-rules are introduction rules that produce a consequent with an extra such connective relative to their antecedents (above the line). In the case of $\neg I$ and $\rightarrow I$, a hypothetical deduction or premise, u, is assumed within the proof of the antecedent, and then discharged when the respective introduction rule applies – u cannot be used anywhere else in the proof. A tautology is a fact derivable with no premises, i.e., with no undischarged hypothetical deductions. It can also be thought of as a fact derivable from an empty theory. Tautologies are always true, with any valuation.

Certain basic tautologies cannot be derived in minimal logic, most notably the law of the excluded middle, $p \vee \neg p$, and the law stating that anything can be proved from falsehood, $\neg p \rightarrow (p \rightarrow q)$. When minimal logic is extended with this rule:

$$\bot/\phi EFSQ$$

EFSQ and the law of the excluded middle are both rendered with the name of the rule elided to the rule itself. When we instead extend minimal logic with this rule:

$$\neg\neg\phi/\phi\neg\neg$$

we obtain a classical logic, which can derive the law of the excluded middle as well. When researchers refer to propositional logic, they are usually referring to either classical or intuitionistic logic. Intuitionistic logics are particularly popular in logical approaches to computing, including computational linguistics.

First-Order Predicate Logic First-order predicate logic is obtained from propositional logic by making two major changes. First, we carry the level of linguistic decomposition one step further. Rather than using variables to refer to primitive truth-valued statements, such as *Felix is sitting on a mat*, we use them in predicate logic to refer to the entities in the world that are mentioned in those statements. A variable would be used to refer to the mat that Felix is sitting on, for example. An assignment function, which replaces valuations, maps these variables to elements of a domain, the collection of entities in the world. We also add constants, which always refer to the same entity regardless of the assignment function, such as Felix. Expressions for truth-valued statements are then obtained by applying predicates to zero or more variables and constants. The predicate for *sit* could take either one or two arguments, depending on how location is encoded in the expression, but one of them would definitely be the constant, *Felix*. An interpretation tells us which domain element every constant stands for and when each predicate is true, as a function of its arguments' domain elements. An interpretation also interprets functions as mapping from one domain element to

another. An expression for *Felix chases Felix's tail*, for example, might be *chase*(*Felix*,*tail*(*Felix*)), wherein *tail* is a function symbol that maps the domain element for *Felix* to the domain element for his tail.

The second major change involves the introduction of quantifiers. Natural language has many quantifiers (*see* **Quantifiers: Semantics**), but standard first-order logic considers only two: universal quantification ($\forall$), which corresponds to *every* or *all*, and existential quantification ($\exists$), which corresponds to *some* or the indefinite article *a*(*n*). One possible expression for *Felix is sitting on a mat*, for example, would be $\exists m.\mathrm{mat}(m) \wedge sit(Felix, m)$. In this formula, the quantifier is identified with the variable that it changes the interpretation of (m), called a bound variable, and then the formula over which this change is effected, called its scope, is explicitly stated. Note that common nouns such as *mat* are generally not expressed as constants, but rather as properties – one-argument predicates – with a quantified variable argument.

The deductive system for either classical or intuitionistic logic can be extended to one for first-order predicate logic by adding elimination and introduction rules for *forall* and $\exists$. This logic is called 'first-order' because the quantifiers quantify over elements in the domain. A second-order logic would permit quantification over sets of elements; a third-order logic would permit quantification over sets of sets of elements, etc.

Higher Order Logic and the Lambda Calculus Predicate and propositional logics can be extended in several ways. Many incorporate extra connectives for expressing necessity, possibility, and belief (*see* **Modal Logic**). A more general extension based on the simply typed lambda calculus captures modal operators as well as all of the higher order extensions of predicate logic, and is widely used in semantics and computational semantics research. The language of the simply typed lambda calculus begins with a set of basic types, consisting in linguistic applications of at least *e* for entities, and *t* for truth values, but often of other types for representing various aspects of the context of an utterance, or possible worlds, hypothetical states of the world, or context as it could have been. The set of all types is formed by computing the functional closure of these basic types. The type $e \rightarrow t$, for example, would be assigned to the properties that encode common nouns, such as *mat*, because they map entities to truth values. Quantifiers and quantified noun phrases are generally given higher order types, such as $(e \rightarrow t) \rightarrow t$, which are also included. Often a bracketed notation is used in place of arrows, with $\langle e, t\rangle$ for $e \rightarrow t$, and $\langle \langle e, t\rangle, t\rangle$ for $(e \rightarrow t) \rightarrow t$.

A typed language assigns a type to each of its expressions. The languages of propositional and predicate logic have no explicit type systems, but they bear a certain resemblance to the expressions of the lambda calculus. This language also has variables and constants, but it has one set of each for each type. Because some types are functional, these are all of the primitive components that we need. Predicates such as *mat*, for example, can be treated as constants of type $\langle e, t\rangle$. Even Boolean connectives such as $\neg$ or $\wedge$ can be treated as constants of type $\langle t, t\rangle$ and $\langle t, \langle t, t\rangle\rangle$, respectively. Expressions in the lambda calculus are formed by successive applications and abstractions over the variables and constants of the language. An application applies an expression of a functional type to an expression with a matching argument type: *mat* can be applied to the *e*-typed variable, x, or to the *e*-typed constant, *Felix*, because it has the type $\langle e, t\rangle$, thus yielding a *t*-typed expression $mat(x)$ or $mat(Felix)$ (even though Felix is not a mat), respectively.

Abstraction is where the innovation of the lambda calculus is to be found. Our usual mathematical notation for defining functions, such as $f(x) = x + 3$, tells us only that f is a function by demonstrating to us an instance of its usage as a function with the dummy argument, x – nothing about the name indicates this, except the unwritten convention that f, g, and h are generally used as function names. Just as predicate logic uses the symbols $\forall$ and $\exists$ to indicate explicitly that a variable will have a quantified interpretation within an explicit scope (as opposed to agreeing that the names a, b, and c will always be used for universally quantified variables), the λ operator of the lambda calculus defines a function over explicitly bound argument variables. For any τ-typed expression, ϕ, and any σ-typed variable, x, we can abstract ϕ to an expression, $\lambda x.\phi$, with the functional type $\langle\sigma,\tau\rangle$. Thus $\lambda x.\phi$ does not even require a conventional name like f – its structure tells us that it is a function, and that occurrences of x within ϕ (if there are any) refer to the argument passed to the function.

The language of the simply typed lambda calculus can be viewed as a generalization of predicate logic because quantified formulas such as $\forall x.\phi$ can be represented as $every(\lambda x.\bar{\phi})$, where *every* is a constant of type $\langle\langle e, t\rangle, t\rangle$, and $\bar{\phi}$ is the corresponding generalization of ϕ. This notation separates the meaning of the quantifier from its syntactic use as a variable binder. Thus, we can also speak of $some(\lambda x.\bar{\phi})$, $most(\lambda x.\bar{\phi})$, etc., all of which have some effect on the interpretation of x within $\bar{\phi}$. When natural language quantifiers are treated in this way, essentially as properties of properties, then they are known as generalized quantifiers. Like predicate logic, an assignment function is required to tell us how to interpret unbound variables. The collection of

domains, one for each type, that enumerate for us the entities in the world of that type is called a frame, and is used along with an interpretation to form a model for this language. The lambda calculus is a set of rules that can be applied to these expressions, much like the deductive systems of propositional and predicate logic. Unlike the rules of logic, however, the aim of the lambda calculus set of rules is not to prove the truth of expressions – many expressions in this language have types other than t, after all – but rather to reduce expressions to simpler but still equivalent forms. Of particular note are three axioms of this calculus, i.e., rules with no antecedents that state the primitive steps of the reduction:

1. α-Reduction, or α-conversion: every expression can be reduced to an expression in which variables have been consistently renamed. For example, $\lambda x.mat(x)$ can be α-reduced to $\lambda y.mat(y)$.
2. β-Reduction: every application of a function can be reduced to substitution of the argument for the bound variable of the function. For example, $\lambda x.mat(x)\,)(m)$ can be β-reduced to $mat(m)$ by substituting m for the occurrences of x in the body of the lambda expression.
3. η-Reduction: certain abstractions are vacuous. For example, $\lambda x.mat(x)$ can be reduced to just mat.

Of these, β- and η-reduction are the most important. Both contain side conditions to ensure that eliminating a λ and its bound variable through argument substitution or deletion will not accidentally bind or unbind other variables, and this is achieved through α-conversion. An expression that can be made no simpler by this calculus is said to be in $\beta\eta$-normal form. For example, $every(mat)$ is the $\beta\eta$-normal form of $every(\lambda x.(mat)(x))$.

An important property of the calculus, called the Church–Rosser property, is that if A can be reduced to either B or C, then there is a D to which both B and C can be reduced. This means that reduction steps can be applied in any order, because the same ultimate result will be obtained.

Substructural Logics In standard classical or intuitionistic logic, premises can be used any number of times (including zero). Another common variation gives propositional or predicate logic a sensitivity to the number of times that premises can be used in a deduction. Proof systems for these linear logics are sometimes used for deriving semantic forms from syntactic structures, because they capture an intuition that lexical items and phrases can and must be used exactly once in such a derivation (*see* **Compositionality: Semantic Aspects**). This can be combined with a sensitivity to the order of premises in a deduction, by distinguishing left-implication (written \) from right-implication (written /). So, in the case of sequences x, x/y or y/x, x, it is possible to derive y, but not in the case of x/y, x or x, y/x.

Categorial grammars use such an ordered variant of propositional logic (specifically, the multiplicative fragment of noncommutative linear logic) for representing the syntactic derivations of grammaticality. In this approach, all but a few semantically primitive syntactic categories are replaced by order-sensitive, linear implications. Verb phrases, for example, generally receive a category such as $np\backslash s$, which means that they combine with noun phrases on their left to form sentences. Proofs that witness the derivation of the sentential category, s, are then sometimes used in place of trees as representations of syntactic structure, although they normally cannot be read with the same seriousness of commitment to the existence or absence of specific constituent phrases. Categorial grammars typically associate expressions from a typed higher order logic with every syntactic category in a derivation, which means that logical representations are being used both in the syntax and in the semantics (*see* **Semantics in Categorial Grammar**). Combinatory categorial grammar uses an implicational notation for its categories similar to that of categorial grammar, but it is a string algebra for mildly context-sensitive languages (see later, Featural), not a logic.

In knowledge representation and planning, it is generally the set of inference rules or implications available for inference that is extended, rather than the underlying formal language of first-order logic (*see* **Inference: Abduction, Induction, Deduction**). Neither of the two most well-known extensions, the situation calculus or the event calculus, has been widely used in computational linguistics until recently. The event calculus is now being used by semanticists as a means for reasoning about aspect in nominals (Hamm and van Lambalgen, 2004), but even this has not yet found its way into more computational work.

Description Logics One trend that has greatly influenced both knowledge representation and symbolic CL has been the development of designer description logics for reasoning through conceptual classifications of entities in the world. Fundamentally, description logics are simply modal logics with better marketing, but syntactically, they normally take the form of simple constraint systems for describing complex objects. These are the same kinds of constraint

languages used in symbolic CL to reason about large-scale featural representations, as well as about logical expressions. Much of what is published under the rubric of 'computational semantics' is actually very syntactic work on devices for assembling logical expressions that can subsequently be interpreted and reasoned with. Increasingly, the CL community has opted not to use the means of combination that exist within the logics of expressions (such as β-reduction within the lambda calculus), but to treat these expressions as trees of subterms that are assembled by conjoining descriptions about them (*see* **Underspecification**). In this treatment, a description logic is used for the descriptions, and the intended models of these descriptions are expressions from the underlying logic used in the semantics.

Discourse Representation Theory Discourse representation theory (DRT) can be thought of as a predicate logic with parochial conditions of scope and variable binding in order to better reflect the behavior of anaphoric expressions in natural language. It is also the first, and still one of the few logical approaches to natural language that treats entire texts as the basic unit of interpretation, rather than sentences in isolation. The latter is typified by Montague semantics, to which DRT was a reaction, historically.

Superficially, sentence boundaries may not seem to play a significant role in semantic interpretation, because in many circumstances, they can be treated as though replaced by a coordinating conjunction, such as *and*. The sequence of sentences, *John knows Mary. He loves her.*, probably does have the same meaning as *John knows Mary and he loves her.*, namely, the conjunction (with Boolean $\wedge$) of the meanings of the individual clauses. The situation becomes rather more complicated in the presence of quantifiers, however. In the case of *A man knows Mary. He loves her.*, the variable representing *he* must be bound by the existential quantifier introduced by the indefinite article *a*. This means that the scope of quantifiers can, in principle, extend beyond the sentence(s) in which they are lexically realized. In the case of *Exactly one boy knows Mary. He loves her.*, however, the uniqueness of the quantifier does not extend to the variable representing *he*, i.e., there are not even other boys who know Mary but do not love her. Perhaps the most essential contribution of DRT to natural language semantics was in showing that introducing a referent into a discourse and predicating on an already introduced referent require two very different treatments in a formal logic.

Logic Programming As attractive as logic is as a flexible and formal expressive device, it does not have much to recommend itself in terms of tractability. Recognition with Lambek categorial grammars was recently proved to be NP(nondeterministic polynomial time)-complete, and many of the proof search and inference problems that we would like to solve in other logics are simply undecidable. Another use of logic has been to encode search problems from more tractable formalisms in order to combine the advantages of both.

The basic algorithms for parsing with context-free grammars (CFGs; see later, and *see* **Chart Parsing and Well-Formed Substring Tables**) were known by the early 1970s. The subsequent search for more elegant and expressive means of writing this kind of grammar coincided with the development of a class of declarative programming languages called logic programming languages, of which Prolog is still the best known example. The idea that a grammar could be viewed as a program written in such a high-level language was a great source of inspiration for symbolic computational linguistics throughout the 1980s. This view, often called 'parsing as deduction,' after the title of a well-known paper on this subject, has since been routinely misinterpreted as 'parsing is deduction,' with the result that the flurry of recent developments in algebraic and functional programming have left symbolic CL behind. Prolog is still widely used in symbolic CL, in spite of the existence of these other programming paradigms, notably constraint programming techniques such as constraint handling rules (Morawietz, 2000), as well as logic programming languages that are arguably better suited to order-sensitive deductions (Polakow, 2001).

Prolog compilers come equipped with a macro notation that hides the encoding apparatus necessary to simulate CFG recognition with Prolog's standard proof search. Grammars written in this notation, called definite clause grammars, are expanded at compile time by converting each nonterminal symbol into a Prolog predicate that contains two extra arguments, representing a difference list. These delimit the starting point and ending point of the substring consumed by that nonterminal. The grammar in Figure 3A, for example, is expanded into the Prolog program in Figure 3B. No parsing algorithm needs to be provided. Definite clause grammars automatically use a top-down, depth-first algorithm simply by using Prolog's built-in search strategy.

There is no equivalent encoding standard for surface realization from CFGs in Prolog. Indexing semantic forms in a lexicon is a much more difficult task, compared to looking up words. A very common method, semantic-head-driven generation (Shieber *et al.*, 1990), proceeds top-down from the goal (usually, the category for sentence and a semantic form) to

A	B
s → np, vp.	s (A, B) :-np (A, C), vp (C, B).
np → det, n.	np (A, B) :- det (A, C), n (C, B).
vp → v, np.	vp (A, B) :- v (A, C), np (C, B).
det → [the].	det ([the | A], A).
n → [man].	n ([man | A], A).
np → [mary].	np ([mary | A], A).
v → [sees].	v ([sees | A], A).

Figure 3 A definite clause grammar (A) and its expansion into a Prolog program (B).

a pivot, the lowest node in the parse tree that has the same semantics as the goal, and then proceeds bottom-up back to the root node of the tree, recursively generating all of the nonpivot daughters top-down at each step. Pivots are generally heads of constituents, which are useful to find early because they contain information about how to combine the syntactic and semantic properties of their arguments. This combination of top-down and bottom-up processing makes generation less prone to nontermination, but is not as transparently encodable in Prolog's built-in search strategy.

Graphical

Graphical representations use graphs, with sets of vertices connected by edges (*see* **Graph Theory**), either to represent dependencies among various entities or to represent states in a process. In symbolic CL, they are used for both.

Trees: Context-Free Grammar Derivations A tree is a connected, acyclic graph. A phrase structure tree, as shown in Figure 4, depicts the assignment of constituency to the substring of a grammatical phrase or sentence. This substring can be read from the vertices at the bottom of the tree (leaves), and is known as the yield of that tree. Each (in this case, labeled) nonleaf vertex corresponds to a constituent, and there is an edge connecting that vertex to each of its subparts, often known as daughters. Constituents are not very easy to define formally, but they appeal to a combination of intuitions about semantic interpretation, grammatical intersubstitutability, lexical items, word order, and constraints on discontiguity that are meant to indicate how a natural or intuitive grammar should refer to the component parts of a phrase. The local shape of a phrase structure tree is often determined in deference to certain regularities of constituent structure observable across major phrasal categories (*see* **X-Bar Theory**).

Phrase structure trees are also a way of representing derivations of a string relative to a context-free grammar (*see* **Chart Parsing and Well-Formed Substring Tables**). Context-free grammars are perhaps the

Figure 4 A phrase structure tree with the yield *John sees the man with the telescope*. Although this string admits two readings, the tree tells us that *telescope* modifies *man*, not *sees*.

oldest form of grammars for human languages, said to date back to the classical Sanskrit grammars of Panini and Patanjali, although the preoccupation there with rule ordering and default reasoning in grammar specification (*see* **Rule Ordering and Derivation in Phonology**) gives those grammars a very different feel compared to their modern analogues. In the mid-20th century, transformational models of grammar rejected the adequacy of CFGs for describing the syntax of human languages, but only for reasons that were either informally sketched or simply mistaken. Interest returned to this issue in the late 1970s and early 1980s, during which several specific constructions (cross-serial verb dependencies in Dutch and Swiss German, reduplication in Bambara morphology) were definitively shown to be outside the grasp of context-free languages.

Trees: Augmentation and Reification Phrase structure trees nevertheless continue to be widely used as representations of syntactic structure. When augmented with additional arcs that indicate movement of constituents from one position in the tree to another, they can be used to model the so-called derivational approaches to syntax, which are generally not context free. When they are annotated to indicate vertices where other trees can be adjoined *in situ*, they become suitable representations for tree-adjoining grammars (TAGs). TAGs characterize a class of mildly context-sensitive languages (*see* **Chart Parsing and Well-Formed Substring Tables**), which include some non-context-free languages, and have been argued to include all human languages (*see*). Alternatively, the simple atomic labels of CFGs, such as noun phrase (NP) and verb phrase (VP), can be replaced with more complex labels, typically feature structures (*see* **Syntactic Features and Feature Structures**),

which, without further constraint, lead to formalisms that admit non- context-free languages. This is the approach taken by lexical functional grammar (LFG) and head-driven phrase structure grammar (HPSG), for example.

Phrase structure trees also remain widely used, with or without these modifications, as derivations from grammars that have been annotated with numerical parameters. The values of these parameters are statistically estimated from corpora of trees (*see* **Parsing: Statistical Methods**; **Parsing and Grammar Description, Corpus-Based**; **Treebanks and Tagsets**), and then used to assign probabilities to the membership of individual strings in the language. Here, the common choice of CFG as the underlying grammar formalism is generally ascribed to efficiency. CFGs admit a dynamic programming algorithm for recognition that runs in $\mathcal{O}(n^3)$ time in the length of the input, as compared to the $\mathcal{O}(n^6)$ algorithm for TAGs, and the undecidability of recognition in unrestricted transformational or feature-structure-based approaches. In addition, not every human language has been proved to be non-context-free, so it may be the case that CFGs are an adequate means of syntactic expression for all but Dutch and Swiss German. This question is still open for English, for example. A CFG can also be viewed as defining an approximation language that contains some non-context-free language of interest plus some ungrammatical strings. If a numerically parameterized CFG can assign probabilities at or near zero to those ungrammatical strings, then the language it induces is arguably a very accurate approximation. The debate over the context freeness of natural language transpired before the use of probability density functions became commonplace in computational linguistics, so the tradeoff between these two points of view still remains poorly understood from a theoretical standpoint.

Looking across the various uses of phrase structure trees, it is important to observe that, in some cases, they are being used to represent derivations relative to strings, usually derivations of membership in a set of strings, whereas in other cases, they serve as first-class objects, which can be tested for membership in a set of trees. The most important difference between strings and tree-based representations of strings is that the additional structure in trees makes those representations nonassociative.

Notions such as context-free languages, context-free grammars, etc. were coined under the assumption that languages are sets of strings. TAGs, on the other hand, view phrase structure trees as objects in their own right that can be substituted into and adjoined to each other. A famous theorem proves that regular languages over trees have yields corresponding to context-free languages over strings. It is actually possible to define tree automata, analogous to string automata (discussed later; see Finite-State Machines), that walk over the vertices of trees to verify their well-formedness. Context-free string languages are also precisely the languages definable by a logic called monadic second-order (MSO) logic. Elucidating the connection between logical descriptions of trees and linguistic theory is currently an active area of research within symbolic CL (Rogers, 1998).

In syntax, optimality theory also considers trees to be objects of study, augmenting their actual construction with a system of constraints that ranks otherwise well-built trees according to how many constraints of grammar they violate. Computational research on optimality theory, however, generally focuses on its phonological applications (*see* **Phonology: Optimality Theory**), in which the objects of study are pairs of strings, and their constraint systems are implemented with finite-state string transducers (see later, Finite-State Machines).

Trees: Variations for Freer Word-Order Languages

Among freer word-order languages, phrase structure trees do not enjoy anything close to the same hegemony over syntactic representation, because of the difficulty in conflating all of the evidence concerning word order, semantic interpretation, etc. onto a single notion of constituent in a single representation. Where trees are used, their branches are often crossed or tangled, in which case they cannot serve as representatives of context-free derivations. In many other approaches, more than one tree is used, thereby allowing for the various criteria for constituency to be separately represented. These include computational work based on autolexical syntax or (*see* **Sgall Petr (b. 1926)**) based on the theoretical work of the Prague linguistic circle (*see* **Jakobson, Roman (1896–1982)**; **Mathesius, Vilém (1882–1945)**; **Trubetskoy, Nikolai Sergeievich, Prince (1890–1938)**). In the latter case, however, the trees differ from phrase structure trees in that every node in the tree is labeled by a word, with heads connected to their arguments or modifiers (Figure 5). Even with fixed word-order languages and single-tree representations, this variety of tree, called a dependency tree, has become quite commonplace in computational linguistics, because it is lexically very well grounded, with the number of nodes being, in most cases, strictly bounded by the number of words in the string to be recognized. The various approaches that use this sort of tree are now collectively referred to as dependency grammar. Symbolic approaches to parsing with dependency grammars, particularly in freer word-order languages, are generally constraint based, which is to say that they

Figure 5 A dependency structure tree with the yield *John sees the man with the telescope*. Unlike the phase structure tree in Figure 4, every node is labeled with a word. Non-leaf nodes are heads, and their daughters are the heads of their arguments. Again, the structure imposed by the tree disambiguates the reading of the sentence.

compute all possible parses by computing the closure of a much richer set of combinations than those implicit in CFG rules (Dechter, 2003) over a much richer set of constraints than 'grammatical substring.' Morphological inflections generally play a very important role in these languages, as do pragmatic distinctions, such as whether a phrase represents given or new information. Word-order restrictions also play a role; there are few, if any, languages with no word-order restrictions whatsoever. What makes freer word-order languages 'freer' is that these restrictions do not uniquely determine a solution, or cannot be stated relative to the usual inventory of phrasal categories that fixed word-order languages use, such as NPs and VPs. Word-order rules stated relative to different categorial inventories, particularly those that are founded in more superficial observations about word order and are orthogonal to semantic interpretation, are called linearization rules (*see* **Word Order and Linearization**).

Trees: Nonsyntactic Uses In addition to syntactic structure, trees are often used to represent derivations from word-formation rules in morphology (*see* **Syntax of Words**) and from prosodic structure in phonology (*see* **Intonation and Syntax; Word Stress**). They are often what guide the composition of logical forms for semantics, and can be annotated with other roles, such as topic and focus, to serve as pragmatic representations as well.

Concept Ontologies Another kind of graphical representation is the so-called ontology. There is very little ontological about them – they are more accurately referred to as epistemological networks. These networks organize concepts (not words) into networks according to primitive semantic relations, most notably the 'IS-*A*,' or hyponymy, relation. Concept *C*1 is a hyponym of *C*2 iff all instances of *C*1 are also instances of *C*2. An example is shown in Figure 6, which is taken from WordNet, currently the most widely used such network in computational linguistics. *Hydromel*, *milk*, etc. are hyponyms of the more general concept, *beverage*. Other relations, such as 'part of' (meronymy) or 'substance of,' are also defined in the network. These networks are used to calculate semantic distances so that applications may 'back-off' their probability estimates to include semantically related concepts that often appear in similar syntactic contexts. Words that denote concepts nearer to the concept, *beverage*, for example, are a better guess for the denotation of the direct object of the verb *drink* than are concepts that are further away.

Semantic distance is generally calculated as an empirically determined distortion of path length, but perhaps the most interesting variation from the standpoint of symbolic CL is the use of least upper bounds. A least upper bound of elements *A* and *B* is the lowest (most specific) concept that is connected to both *A* and *B* from above, i.e., of which both *A* and *B* are both hyponyms. The least upper bound of *milk* and *ginger beer*, for example, is *beverage*, but the least upper bound of *milk* and *honey* is *food*, and the least upper bound of *milk* and *morphine* is the very general concept, *object*. We can then use the depth of the least upper bound, i.e., the length of the shortest path between the least upper bound and the all-encompassing root concept, *entity*, as a measure of how related the two terms are. *Milk* must be semantically closer to *ginger beer* than to *morphine* because its least upper bound with respect to *ginger beer* is deeper.

Concept ontologies can also be found in formal research on lexical semantics (*see* **Lexicon: Structure; Lexical Semantics: Overview**), and bear a very close relationship to the type systems that are used with many featural representations.

Finite-State Machines The third major use of graphical representations in symbolic CL is the finite-state machine. These machines consume strings as input, and either produce a yes/no answer as to whether the string belongs to some language (a finite-state automaton) or produce one of several output strings corresponding to the input according to some relation (a finite-state transducer). In either case, the vertices of the graph correspond to states in the process of consuming the input, and the edges correspond to the consumption of one symbol or token from the input. Figure 7, based on Antworth's (1990) morphology of English, depicts a finite-state automaton that approximates the recognition of well-formed English

Figure 6 A portion of the WordNet ontology. Hyponyms are listed below their concepts and are connected with unlabeled lines; meronyms are denoted by the label 'P' and substances are denoted by the label 'S.' Least upper bounds appear as upward joins of edges.

Figure 7 A finite-state automaton that approximates the recognition of well-formed English adjectives, based on Antworth's (1990) morphology of English. Adapted from Jurafsky and Martin (2000), with permission.

adjectives, wherein the tokens consumed are morphemes or adjectival roots. Some finite-state machines have edges called jump arcs, labeled here with ε, which consume no input on transition.

Finite-state automata recognize exactly the regular languages (*see* **Chart Parsing and Well-Formed Substring Tables**), and finite-state transducers encode exactly the regular relations. Both of these can be combined to form larger machines using a variety of operations that are closed under regular families, such as concatenation, union, composition (in the case of regular relations), and intersection (in the case of regular languages). Although their worst-case running time is exponential, this can be reduced to linear time if the machine can be determinized. A deterministic finite-state machine is one in which there are no jump arcs, and no two edges with the same source state consume the same input. In general, finite-state transducers cannot be completely determinized, but they are often not used to simulate the actual machines that they encode. Instead, they can be used to represent compactly sets of string mappings, particularly when the states or edges can be annotated with probabilities (weighted transducers). Combining these sets to find the most probable mapping for some input is extremely fast in practice, due in large part to some very efficient algorithms for composing two weighted transducers, and minimizing the number of states in a weighted transducer (Mohri, 2004).

Finite state machines are widely used in computational morphology and phonology, and are used to model turn taking and error recovery in grammars of spoken discourse within limited conversational domains. Transducers are also used for text analysis in speech synthesis and the study of writing systems. Weighted transducers are widely used to implement language models in automatic speech recognition.

Featural

Feature structures are a kind of record structure consisting of pairs of features or attributes and values. As shown in Figure 8B, they can also be thought of as graphs with labeled vertices and edges. Although the graph-based notation is very difficult to cope with on a large scale, it is perhaps more indicative of the original motivation for using feature structures: theoretical models of mentation as spreading activations in networks of directed, i.e., labeled, associations.

(C) *throwing* ∧ THROWER:(*index* ∧ PERSON:*first* ∧ NUMBER:(*N* ∧ *singular*) ∧ GENDER:*gend*)
∧ THROWN:(*index* ∧ PERSON:*third* ∧ NUMBER:*N* ∧ GENDER:*gend*)

(D) THROWER:(PERSON:*first* ∧ NUMBER:(*N* ∧ *singular*)) ∧ THROWN:(PERSON:*third* ∧ NUMBER:*N*)

Figure 8 Two common depictions of feature structures, an attribute-value matrix (A) and a labeled graph (B), with two descriptions (C)and (D) that depict them.

The record-based notation in Figure 8A is sometimes called an attribute-value matrix (AVM) in linguistics, although it is not a matrix in any mathematical sense. Regardless of the notation used, feature structures also allow for structure sharing, in which two attributes have (extensionally) the same value. This is a stronger statement than saying that two attributes have indistinguishable values, which is in turn stronger than saying that they have consistent values. In Figure 8, for example, the two GENDER features have indistinguishable values, but they are different (more precisely, there is no evidence to conclude that they are the same). The two NUMBER features, on the other hand, really do have the same value. The choice of representation is often underdetermined by the empirical evidence, but it can have formal consequences when feature structures are unified or inequated.

Feature structures are often no more formally defined than this, with no clear statement of the range of possible values for each feature, and no indication of which features are permitted to co-occur in the same feature structure. To explicate either of these properly, the feature structures must be typed. The treatment of typed feature structures given here mostly follows Carpenter (1992) and conventional practice in head-driven phrase structure grammar. Type systems for feature structures look a great deal like the concept ontologies discussed previously. They are partial orders consisting only of 'IS-*A*' links, although hyponyms are here referred to as subtypes, and the all-encompassing root concept/type is called 'top' (written ⊤) rather than 'entity.' Large HPSGs can have as many as 8000–10 000 types. With each type, we associate a collection of appropriate features. Every feature structure of that type must bear all of its appropriate features (along with a value), and cannot bear any other features. In the most general setting, the values of features are typed feature structures. Even atoms, such as *third* or *singular*, as in Figure 8, are taken to be typed feature structures, whereby these types have no appropriate features.

Each appropriate feature also has a value restriction, of which the type of that feature's value must be a subtype. These constraints on allowable combinations of features and types are called an appropriateness specification, and they can also be used to constrain co-occurrences of features in the same feature structure. A signature is a partial order of types together with an appropriateness specification. Figure 9 depicts a signature that might have induced the feature structure in Figure 8. Appropriateness makes the internal structure of a feature structure much more predictable as a function of the signature, which makes both of them less error prone. The greatest benefit of appropriateness, however, is that it allows us to describe both of them very tersely. In large grammars, typed feature structures can have as many as 100 000 vertices, so instead we use a description logic (as discussed previously) to refer to them. Descriptions consist of types, variables, and negative constraints called 'inequations,' which prohibit structure sharing. The descriptions can be closed under conjunction (∧) and disjunction (∨), as well as feature selection, which means that we can apply parts of a description to a particular feature's value. Appropriateness allows us to infer much of the

Figure 9 A signature for the feature structure in Figure 8.

$$\begin{bmatrix} \text{throwing} & \\ \text{THROWER} & \begin{bmatrix} \text{index} & \\ \text{PERSON} & \text{first} \\ \text{NUMBER} & \text{singular} \\ \text{GENDER} & \text{gend} \end{bmatrix} \\ \text{THROWN} & \begin{bmatrix} \text{index} & \\ \text{PERSON} & \text{third} \\ \text{NUMBER} & \text{singular} \\ \text{GENDER} & \text{gend} \end{bmatrix} \end{bmatrix} \sqsubset \begin{bmatrix} \text{throwing} & \\ \text{THROWER} & \begin{bmatrix} \text{index} & \\ \text{PERSON} & \text{first} \\ \text{NUMBER} & \boxed{1}\ \text{singular} \\ \text{GENDER} & \text{masc} \end{bmatrix} \\ \text{THROWN} & \begin{bmatrix} \text{index} & \\ \text{PERSON} & \text{third} \\ \text{NUMBER} & \boxed{1} \\ \text{GENDER} & \text{neut} \end{bmatrix} \end{bmatrix}$$

Figure 10 Two feature structures that stand in the subsumption ($\sqsubset$) relation. The second structure contains all of the information in the first, plus two more specific types at the GENDER features, and a structure-sharing relation that is consistent with the first structure's type assignment, though absent.

structure that goes unstated in a description, which allows us to make the descriptions shorter. Rather than refer to the feature structure in Figure 8 with the description in Figure 8C, for example, we can use only the description in Figure 8D – the appropriateness of Figure 9 can fill in the rest. This makes grammars more readable, because only the relevant parts of potentially very large feature structures are selected for discussion at any point in a grammar.

Because types are partially ordered, and because some feature structures can have more structure sharing than others, it is possible to speak of feature structures as being partially ordered as well. We say feature structure F subsumes feature structure G iff G conveys all of the information that F does, plus possibly more. Figure 10 shows two feature structures that stand in this relation. Provided that the type system is a join semilattice, it is possible to compute a greatest lower bound of two consistent feature structures with respect to subsumption. This is the dual of the least upper bound mentioned previously (q.v., Concept Ontologies), and corresponds to finding the least informative feature structure that consistently combines their information. The process of computing the greatest lower bound is known as unification (*see* **Unification: Computational Issues; Unification, Classical and Default**), and it is attractive in linguistic settings because each word of a sentence can be viewed as contributing a part of the syntactic or semantic information that the entire sentence conveys. Any kind of agreement, between a subject and a verb, for example, or between an anaphor and its referent, is a prime candidate for a unification-based analysis, since each component of the agreement may only be constrained in its usage by part of the information that they together uniquely convey.

Unification is the fundamental operation performed by nearly every feature-structure-based application in linguistics, but it is often embedded into a number of different control strategies. HPSG uses constraints of the form $\forall\ F.F \sim \tau \rightarrow \phi$, where F is a description variable, τ is a type, and ϕ is a description (which usually contains a reference to F). These principles of grammar state that every F that has type τ or one of its subtypes must also satisfy the description ϕ. Every nondisjunctive description has a unique least-feature structure that it describes, called a 'most general satisfier,' and these constraints are enforced by unifying every τ-typed feature structure with the most general satisfier of ϕ. If ϕ is disjunctive, then the constraint is enforced by nondeterministically iterating through all of ϕ's nonunique minimal satisfiers, until one of them unifies with F.

Grammar formalisms such as HPSG that use these constraints to express principles of grammar are sometimes called constraint-based formalisms, but recognition in these formalisms is nearly always driven by a deductive backbone that the constraints merely augment. In the case of HPSG, that backbone is generally an extended phrase structure rule formalism in which every category is a description of a typed feature structure. Figure 11 provides an example of such a rule. In principle, variables can share structure not only within a single feature structure, but also

(*Mother* $\wedge$ *phrase* $\wedge$ SYNSEM:LOCAL:CAT:(HEAD:*Head* $\wedge$ SUBCAT:*MSubCat*)

$\Longrightarrow$ (*ArgDtr* $\wedge$ *non_word* $\wedge$ SYNSEM:*ArgSynSem*)

(*HeadDtr* $\wedge$ *phrase* $\wedge$ SYNSEM:LOCAL:CAT:(HEAD:*Head* $\wedge$ SUBCAT:[*ArgSynSem* | *M SubCat*]))

Figure 11 An extended phrase structure rule based on the head-subject schema from head-driven phrase structure grammar. Typed feature structure descriptions appear in place of phrase structure categories, and variables are shared across descriptions. The square brackets are a common shorthand for lists.

across daughters of the same rule, and between the mother and a daughter, as shown in Figure 11. Variable sharing in rules such as this is enforced by unification. It is also possible to embed typed feature structure descriptions into a logic programming language such as Prolog for a more flexible degree of control.

Typed feature structures have been used in every level of linguistic representation. Their oldest use in linguistics was in phonetics, for which, borrowing from work on category perception in psychology, they were used with only binary-valued (+/−) features to classify the basic phones of English. Unification played no major role here. Their widespread use in syntax began in the late 1970s with work by Martin Kay, who was interested in a data structure that would support unification more flexibly than the terms of standard first-order logic did. In morphological analysis, finite-state transducers are often extended to emit strings that encode feature structures in order to track agreement and other abstract properties at the morphology–syntax interface. They also figure very prominently in planning and semantics within restricted domains. Interlingua representations are mainly feature structures (*see* **Machine Translation: Interlingual Methods**).

Syncategoremata

G Klima, Fordham University, Bronx, NY, USA

The History of the Distinction

The medieval distinction between syncategorematic terms ('syncategoremata,' such as 'and,' 'or,' and 'not,' which merely combine other terms) and categorematic terms ('categoremata,' such as 'man,' 'Socrates,' and 'animal,' which can be predicated of things) dates back to the 6th-century grammarian Priscian, who in his *Institutiones Grammaticae*, who in his in turn, attributes the idea to certain 'dialecticians.' Syncategoremata were commonly recognized by Stoics and Neo-Platonics (Pinborg, 1972: 60). However, Peripatetic dialecticians could also take their cue from Aristotle's relevant remark on the copula (the verb 'is' or its equivalent, joining subject and predicate), when he says that it is in itself "nothing, but co-signifies some combination, which cannot be thought of without the components" (*On Interpretation*, 16b24–25). In any case, according to Priscian, the dialecticians he refers to characterized syncategoremata in a similar way: such terms merely cosignify, in contrast to verbs and nouns, which, when combined, make a complete expression. With the emergence of the distinctive logical and grammatical literature of the Middle Ages in the 12th century continuing through the late 15th and early 16th centuries, discussions of syncategoremata became part of the characteristic genres of this literature (Sweeney, 2002), in which our medieval colleagues developed ever more sophisticated characterizations of syncategorematic terms, their distinction from categorematic terms, their function, and their nature. According to Norman Kretzmann's (1982) periodization, we can distinguish the following main stages in the medieval career of syncategoremata:

1. Their emergence as the focal points of certain logical or semantic relationships or special problems of interpretation (in the 12th century, especially the latter half)
2. Their identification as a distinguishable set of topics worthy of development in separate treatises typically called syncategoremata (from the last quarter of the 12th century to the last quarter of the 13th century)
3. Their assimilation into general treatises on logic, sometimes as a group but sometimes dispersed in ways designed to associate particular syncategoremata with more general topics in logic to which they are appropriate
4. Their absorption into the sophisma literature (discussions of logical puzzles generated by problem sentences, the so-called 'sophismata'), in which a particular syncategorema may serve as the germ of a paradox the interest of which is often associated with metaphysics or natural philosophy more than with logic or semantics proper (from the first quarter of the 14th century to the disintegration of scholastic logic).

With the decline of scholastic logic, the logical treatises specifically devoted to syncategoremata or to sophismata focusing on the problems generated by syncategoremata became gradually extinct along with the rest of the characteristic logical literature of the Middle Ages. Yet, the distinction between categorematic and syncategorematic terms has never become entirely forgotten, and it keeps recurring in various guises also in modern philosophy. However, the most sophisticated accounts of the distinction are still to be found in the medieval literature, which is the focus of the rest of this article.

Syntactic and Semantic Criteria of Drawing the Distinction

It is interesting that Priscian's remark involved two different and by no means equivalent criteria for distinguishing syncategorematic and categorematic terms. On what may be called the 'syntactic' criterion, categorematic terms are those that can function as subjects or predicates of propositions so that their combination yields a complete proposition, whereas syncategorematic terms cannot be subjects or predicates. On the 'semantic' criterion, however, syncategorematic terms are those that merely cosignify (i.e., signify in combination with some other term) but that in themselves do not signify anything. Apparently, the syntactic criterion provides a good test for sorting various parts of speech into either of the two members of the division. However, even if the criterion works, it does not seem to provide a principled reason why certain parts of speech behave in one way or the other. The semantic criterion seems to provide such a reason, but as it stands, it is rather vague.

Indeed, on closer inspection even the syntactic criterion does not seem to fare much better. First, in the appropriate context any part of speech can be a subject or a predicate. For example, the preposition 'of' or the negation 'not,' which are certainly obvious candidates for being regarded as syncategorematic, can be used as subjects in the sentences '*Of* is a preposition' and '*Not* is a negation,' where they are

taken to stand for themselves (and other token phrases of the same type) or, as medieval logicians would put it, in 'material supposition.' (Cf. the modern distinction between mention and use.) Accordingly, later medieval authors sometimes refined the syntactic criterion by adding the requirement that syncategorematic terms are those that cannot be subjects or predicates when used 'significatively' (i.e., in their proper function) and not with the intent to take them for themselves. However, this refinement clearly indicates that the distinction primarily applies not to words per se but, rather, to their different uses. This point is further reinforced by the fact that parts of speech that on the simple syntactic criterion would be deemed syncategorematic in some of their uses can be subjects or predicates even when taken significatively. For instance, adjectives that cannot serve as subjects on their own can be predicates (e.g., contrast the grammatical 'A man is brave' with the ungrammatical 'A brave is a man'), and they can have substantive uses (in Latin marked by the neuter gender), in which they can even serve as subjects (as in the Latin sentence, *Album est coloratum* '[What is] white is colored,' but even in English we can say, 'Blue is a soothing color'). Furthermore, logicians, who were primarily interested in the semantic features of syncategoremata, would not regard adjectives and adverbs as syncategorematic without further ado.

Therefore, to distinguish such terms from syncategoremata pure and simple, they introduced a further distinction. The two most influential authors of the 13th century on this topic, William of Sherwood and Peter of Spain, both distinguished 'pure categoremata' (i.e., subjects and predicates) from their dispositions or determinations (Peter of Spain, 1992: 38–41; William of Sherwood, 1941: 48). However, they also distinguished those dispositions of subjects and predicates that belong to them insofar as they are subjects and predicates (such as 'signs of quantity,' i.e., quantifiers), the pure syncategoremata, and those dispositions that belong to the things that are signified by subjects and predicates regardless of the fact that they are subjects and predicates. The latter are just categorematic dispositions of pure categoremata, such as adjectives and adverbs. For example, in the proposition 'Every wise man is running,' the pure syncategorematic term 'every' is a determination of the subject term of this sentence in relation to the predicate, determining that the sentence is true only if the predicate applies to everything that falls under the subject. Thus, 'every' applies to the subject insofar as it is the subject of the predicate of this sentence. However, the determination 'wise' pertains to 'man' regardless of what the latter is subjected to and how. This determination merely determines that of all man only the wise are considered (i.e., those things that have the property signified by the adjective).

Thus, adjectives and adverbs, even in their purely adjectival or adverbial uses, on this criterion are no longer regarded as pure syncategoremata, even if they cannot be self-standing subjects or predicates. Rather, they are regarded as categorematic parts of complex subjects and predicates signifying the dispositions of the things signified by nouns and verbs, the principal parts of such complex subjects and predicates.

Further refinements of the distinction were provided by the nominalist philosophers of the 14th century (*see* **Nominalism**), such as William Ockham, John Buridan, and Albert of Saxony, with reference to their conception of a 'mental language,' a natural system of representation constituted by mental concepts, the mental acts of a human mind to which spoken or written parts of speech are systematically subordinated, rendering these spoken or written signs meaningful (*see* **Mentalese**). In this setting, any part of a spoken or written language is said to signify immediately the concept to which it is subordinated, and it is said to signify ultimately the object or objects conceived by means of the concept to which it is subordinated (Buridan, 2001: xxxiv–xli). However, since some concepts have only the function of combining simple concepts into complex ones (e.g., a mental copula or conjunction), or just to modify the representative function of other concepts (e.g., a mental term-negation), but in themselves do not have the function of representing any objects, such concepts themselves are syncategorematic in mental language. Thus, the purely syncategorematic terms of spoken or written languages will be those that are subordinated to such syncategorematic concepts.

For example, as Buridan (2001: 234) remarks,

> The copulas 'is' and 'is not' signify different ways of combining mental terms in order to form mental propositions, and *these different ways [of combining] are in their turn complexive concepts*. . . . And so also the words 'and,' 'or,' 'if,' 'therefore,' and the like designate *complexive concepts* that combine several propositions or terms at once in the mind, but nothing further outside the mind. These words are called purely syncategorematic, because they signify nothing outside the mind, except along with others, in the sense that the whole complex consisting of categorematic and syncategorematic words does signify the things conceived outside the mind, but this is on account of the categorematic words.

Buridan's younger contemporary, Albert of Saxony (1974: f. 2v), provides further clarification of what we should understand by the significative function of syncategorematic terms when he observes:

> If the terms 'every,' 'no,' etc. are taken materially, then they certainly can be subjects or predicates of propositions, as when we say 'Every is a universal sign,' or 'Or

> is a [disjunctive] conjunction,' or 'No is an adverb,' or 'And is a copulative conjunction.' For in these propositions these words are not taken significatively, since *they do not exercise the function [non exercent officium] which they were imposed to exercise*. So, in the proposition 'Every is a universal sign,' 'every' does not distribute anything, in 'No is an adverb,' 'no' does not negate anything, and likewise, in 'And is a copulative conjunction,' 'and' does not copulate anything; therefore, in these propositions these terms are taken not syncategorematically, but categorematically.

Therefore, syncategorematic terms, when they are taken significatively, are imposed to exercise the logical functions of modifying the semantic functions of categorematic terms with which they are construed on account of being subordinated to mental acts that exercise these functions on the mental level. Indeed, as Albert of Saxony (1974: f. 3r) notes, this is precisely the reason why in their significative function they cannot be subjects of predicates. Thus, Albert presents the semantic distinction on the mental level as the ultimate reason for the syntactic criterion of the distinction on the spoken level. Indeed, later medieval treatises (in the late 14th and early 15th centuries) on concepts and mental language, such as those by Thomas of Cleves, Paul of Gelria, or Peter of Ailly, draw the distinction as pertaining directly and primarily to acts of the mind. These authors describe 'mental categoremata' as being acts of conceiving of some objects, as opposed to 'mental syncategoremata,' which are rather different modes or ways of conceiving of the objects conceived by the former (Bos and Read, 2001: 14, 54–57, 96, 130; Peter of Ailly, 1980: 18–19; see also the previous quote from Buridan). From this characterization, and from the common medieval doctrine that the semantic functions of spoken and written terms are determined by the semantic functions of the concepts to which they are subordinated, we get as a simple corollary the usual semantic and syntactic features of (pure) syncategoremata, namely that they are cosignificative rather than significative on their own, and that taken significatively they cannot be referring terms of propositions.

Although the distinction drawn in these terms was not in vogue in early modern philosophy, it is significant that John Locke would characterize the parts of speech he calls 'particles' (but that his medieval colleagues would recognize as syncategoremata) as being "marks of some action or intimation of the mind" – that is, some mental operation on ideas of the mind (Locke, 1995: bk. IV, c. 7, n. 4). Later, Immanuel Kant would describe pure concepts of understanding as 'logical functions,' directly preparing the way for Gottlob Frege to describe quantifiers as 'second order concepts' (i.e., as concepts operating on concepts).

Philosophical Significance of the Distinction

Syncategorematic terms present a particular problem for those philosophers who would take the primary function of elements of a language to be the signs or names of things. For in the case of syncategorematic terms, we just do not seem to have obvious candidates among things in the world for these terms to name. Nevertheless, medieval realists, such as Peter of Spain or William of Sherwood, or the modistic grammarians of the 13th and 14th centuries, such as Thomas of Erfurt (for further references, see Zupko, 2003), who professed a close parallelism between *modi significandi* (modes of signifying), *modi intelligendi* (modes of understanding), and *modi essendi* (modes of being), assumed in their ontology certain modes of being or dispositions of things corresponding to the modes of signifying determined by modes of understanding conveyed by syncategorematic terms. Therefore, in this framework, syncategorematic terms do have counterparts in reality: the modes or dispositions of things that 'prompt' us to conceive of and hence signify things in certain ways.

Although these philosophers, logicians, and grammarians were careful to attach only a certain diminished degree of reality to these dispositions, nevertheless, it was precisely their 'ontological liberalism' that prompted William Ockham and his nominalist followers discussed previously to identify syncategoremata primarily with the mental acts modifying the representative function of categorematic concepts. For in this nominalist framework, syncategorematic terms simply have no extramental counterparts: the complex expressions they form with categorematic terms signify only the things signified by the categorematic terms, but in different ways. Thus, for example, as Buridan explicitly concluded, the proposition 'God is God' and the proposition 'God is not God' signify extramentally exactly the same thing as the term 'God' does, but this does not render these expressions synonymous; they signify the same thing differently because of the different syncategoremata signified by them in the mind (Buridan, 2001: 234). This is how late-medieval nominalists were able to have a parsimonious ontology along with a sufficiently 'fine-grained' semantics, by making the necessary semantic distinctions on the conceptual and not on the ontological level.

In addition to these and similar ontological considerations, the reinterpretation of the medieval distinction had even more far-reaching consequences in

early modern and modern philosophy with Kant's reclassification of a number of traditional metaphysical concepts, such as substance and accident, cause and effect, existence, necessity, and possibility, as concepts of pure understanding – that is, as logical functions or syncategoremata. Kant's considerations, especially those concerning existence, directly paved the way for Gottlob Frege's analysis of the notion of existence as a second-order concept, the existential quantifier, which in turn could immediately be exploited by the anti-metaphysical program of logical positivists, such as Rudolf Carnap (1959). Accordingly, without the recent reevaluation of the concepts of existence, possibility, and ontological commitment in the framework of modern possible-worlds semantics, metaphysics probably still could not be regarded as the legitimate philosophical subject in analytic philosophy it has become in the past few decades. As even this example shows, our actual understanding of the medieval distinction still has fundamental significance in our considerations concerning the relationships between language, thought, and reality.

Synchronic and Diachronic Variation

T Nevalainen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Background

This article discusses alternative ways of saying the same thing, and the generalizations that apply to this linguistic variation both at present and across time. It is the alternative expressions available at a given time that provide the foundations for processes of language change.

Generally speaking, language can be analyzed both synchronically, as it is at a particular point in time, and diachronically, as it changes across time. Introducing these terms in his *Cours de linguistique générale* (1916), Ferdinand de Saussure notes: "Everything that relates to the static side of our science is synchronic; everything that has to do with evolution is diachronic" (de Saussure, 1916 [1978: 81]).

The historical study of language also presupposes the study of periods of time understood as synchronous and therefore static. An individual speaker, de Saussure maintains, is always confronted with language as a state. More recently, however, sociolinguistic research has shown that language existing at a particular time need not be viewed as static and invariant. This supports the everyday observation that the same meaning can be expressed in various ways under different circumstances. Alternative expressions are most obvious in vocabulary. In English we can choose, for instance, between *answer* and *reply*, *courteous* and *polite*, or *mobile* and *cell phone*. Syntactic

Synchronic and Diachronic Variation

T Nevalainen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Background

This article discusses alternative ways of saying the same thing, and the generalizations that apply to this linguistic variation both at present and across time. It is the alternative expressions available at a given time that provide the foundations for processes of language change.

Generally speaking, language can be analyzed both synchronically, as it is at a particular point in time, and diachronically, as it changes across time. Introducing these terms in his *Cours de linguistique générale* (1916), Ferdinand de Saussure notes: "Everything that relates to the static side of our science is synchronic; everything that has to do with evolution is diachronic" (de Saussure, 1916 [1978: 81]).

The historical study of language also presupposes the study of periods of time understood as synchronous and therefore static. An individual speaker, de Saussure maintains, is always confronted with language as a state. More recently, however, sociolinguistic research has shown that language existing at a particular time need not be viewed as static and invariant. This supports the everyday observation that the same meaning can be expressed in various ways under different circumstances. Alternative expressions are most obvious in vocabulary. In English we can choose, for instance, between *answer* and *reply*, *courteous* and *polite*, or *mobile* and *cell phone*. Syntactic

structures similarly have variant realizations: *there are apples in the bowl/there's apples in the bowl*, *I don't want anything/I don't want nothing*.

The systematic study of synchronic linguistic variation goes back to the rise of sociolinguistics in the 1960s. In studies of linguistic variation, the variant forms expressing the same meaning constitute a linguistic variable. Since these variants have the same basic content, the choice of one over another is not made on semantic grounds. The variant forms typically correlate with other linguistic elements and external variables such as the speaker's age, sex (often viewed in terms of the social notion of gender), social class or other group membership, and register or contextual style.

Since variation in pronunciation readily fulfills the requirement of semantic equivalence, it has received by far the most attention in sociolinguistics. A much studied issue in Englishes around the world is the realization of the suffix *-ing* (as in *singing*, *dancing*) or, using sociolinguistic notation, the (ing) variable, which can be pronounced either with a velar nasal [ŋ] or an alveolar nasal [n]. Syntactic variables (such as the *was/were* and multiple-negation variables illustrated above) have also attracted research, as has morphological variation, including issues such as the choice between the two-part negator *ne* ... *pas* and simple *pas* in French.

Morphophonemic variation is of particular interest in languages with a rich inflectional system such as Finnish, in which reduced forms can alternate with full ones. This happens, for instance, with the first- and second-person pronouns *minä* 'I' and *sinä* 'you', which in colloquial speech are reduced to [mæ] and [sæ], respectively. In historical studies, phonological variation often falls outside the scope of empirical research, and morphological and syntactic alteration are investigated even in a language such as English, which shows a sharp reduction in inflectional variation over the centuries.

Lexical variation has received less attention by sociolinguists, partly since it may not always be easy to show that two or more words have precisely the same meaning. Another reason for sociolinguists' relative lack of interest in lexical variation may be their concentration on variation within localized dialects. By contrast, there is a long tradition in the study of lexical variation in dialectology, which has produced dialect atlases mapping regional dialect forms, especially in languages spoken in Europe or of European descent. In recent years, lexical variation has found a place in sociolinguistic studies of language and dialect contact. They explore issues ranging from the choice between *running shoes*, *runners*, and *sneakers* or between *soft drink* and *pop* in Canadian English to the number of loan words from Arabic, French, and English in Wolof speakers' vernacular usage in Senegal.

Variation in discourse patterns has also been studied by sociolinguists to some extent, although the notion of a linguistic variable as a choice between variant forms is not always directly applicable to discourse. Many studies have instead focused on the frequency of use by different social groups, e.g., men and women, of forms such as tag questions and other pragmatic expressions (e.g., *tu sais*, *vous savez*, *n'est-ce pas* in French, and *you know*, *you see*, *I mean* in English). Larger issues such as gender and social class differences in the use of politeness strategies and speech styles have also been reported.

Sociolinguistic research has come of age in that it has produced some major generalizations about linguistic variation across languages and language communities robust enough to qualify as sociolinguistic facts. Most of the facts about linguistic variation discussed below present discoveries made within the quantitative paradigm. This branch of sociolinguistics is also known as variation theory because it analyzes linguistic variation and as correlational sociolinguistics because it connects linguistic and social variation. The use of the term 'social' is here applied to a whole range of external factors that are found to correlate with linguistic variation. More recently, the term 'social dialectology' has come to be used to mark the close relation between sociolinguistics and traditional dialectology – after all, both fields investigate linguistic variation.

This article also views sociolinguistic facts from a diachronic perspective. It shows that these generalizations based on present-day data hold for the past and can be demonstrated for earlier stages of historically well-documented languages. For reasons of space, and reflecting the amount of empirical research available, most of the historical illustrations come from English. A seminal work in the field is Suzanne Romaine's monograph *Socio-historical linguistics* (1982), which discusses relativization strategies in Older Scots as a case of synchronic variation sensitive to register differences. The genres studied by Romaine included official and legal prose, literary and epistolary prose, and verse of different kinds. A few more words will be said about historical variation studies before comparing the present with the past.

Historical Sociolinguistics

In recent years, historical sociolinguists have put the general findings made on present-day linguistic variation to the test of time. The basic assumption for doing so is based on a uniformitarian notion, which can be formulated as follows: "the principles

governing the world . . . were the same in the past as they are now" (Lass, 1997: 25).

Language change presupposes variation. It can therefore be argued that since human languages have changed, they must have varied in the past. However, the uniformitarian notion does not license any direct application to the past of modern sociolinguistic constructs such as social class. It merely implies that since social variation and interaction pattern with linguistic variation today, we have every reason to expect that to have been the case in the past as well. What the patterns themselves were remains an empirical issue. The empirical study of sociolinguistic facts of the more remote past is confined to languages with a written history that gives access to variable linguistic data. For the majority of the world's languages, such data unfortunately do not exist. For most European vernaculars, reconstructing language use in its social context is a question of time depth: even the late medieval sources may often be too fragmentary to provide a reliable basis for sociolinguistic investigations.

As far as English is concerned, the situation begins to look brighter from the 15th century onward when full vernacular literacy, the ability to both read and write, starts to spread outside professional circles. According to David Cressy's study based on people's ability to sign their names, an average of 10% of men and 1% of women could both read and write in England in 1500. By 1700, the corresponding figure had risen to 40% for men and 25% for women. As literacy studies give an idea of the kind of people whose language has been recorded in writing, they constitute a vital part of the historical research relevant for sociolinguists. A deeper understanding of the social circumstances of the past is provided by research into social, economic, cultural, and demographic history. The scholarship in these fields is of course limited by the data sources available but less so than in historical linguistics, where actual language data are required.

What was written and, more importantly, what has survived from the later Middle Ages onward is nevertheless quite impressive. A long diachronic continuity can be traced for vernacular genres such as statutes, a vast array of documents of different kinds, religious and secular instruction, the Bible, medical and other scientific writings, chronicles and histories, fiction and drama, and personal correspondence. Structured, computerized collections of texts (corpora) that contain chronological data from different time periods have proved invaluable for historical sociolinguistics.

Electronic corpora make it comparatively easy to obtain quantitative data on linguistic variation. Below is a computer-generated list (concordance) that presents all instances of the two alternative subject forms, *ye* and *you*, of the pronoun *you* that Thomas Elyot uses in a passage of *The Governor* (1531), one of the texts included in the *Helsinki Corpus of English Texts*. Each line begins with information encoded in the electronic text, which here includes the period of writing (E1 = 1500–1570) and a page reference to the source text. The sample concordance shows that in this passage the author preferred the traditional subject form *ye* in 10 cases out of 14 but also used the incoming form *you* four times.

E1 150: in this wise; Be **you** angry and loke that
E1 150: and loke that **you** sinne nat. And
E1 151: trespas, or, if **ye** do nat, strike me
E1 151: of the booke that **ye** wrate. And diuers
E1 153: howe worthy had **you** ben (if god had
E1 153: a christen prince, **ye** mought haue showed
E1 154: treasure suppose **ye** shulde I nowe haue,
E1 154: and kept money as **ye** exhorte me to do?
E1 154: said Cyrus, sende **ye** some man, whom ye
E1 154: ye some man, whom **ye** best truste, with
E1 155: P155 loke that **ye** take me for a man
E1 155: accounte, if **ye** can, how moche
E1 155: said, Howe thinke **you**, Cresus, haue I nat
E1 155: I nat tresure? And **ye** counsailed me that

Corpora consisting of many genres such as the *Helsinki Corpus* provide information on usage-based differences in language variation and change. In recent historical sociolinguistic work, this information is supplemented by designing corpora that enable the study of user-based variation. Personal letters, in particular, supply material produced by individuals whose life-histories have also been recorded for posterity. Material like this allows the correlation of language variation with speaker variables. One such resource is the *Corpus of Early English Correspondence*, compiled for the study of the social embedding of language change in Renaissance English.

Sociolinguistic Facts

Linguistic Variation Is Not Categorical

Perhaps the broadest generalization that can be made based on modern sociolinguistic research is that links between linguistic variables and other variables correlating with them are probabilistic (more or less) rather than categorical (either present or absent). The use of the (ing) variable is probabilistic, firstly, because English speakers use both the alveolar and the velar variant and, secondly, because they do so to varying degrees. There is no change under way, as neither variant appears to be gaining ground at the expense of the other. The fact that the social and linguistic embedding of variant forms in general is a

matter of more or less also provides the key to understanding the diffusion of linguistic changes across time and speech communities.

Present-day sociolinguists use an apparent-time construct to capture real-time change under way. The apparent-time model is based on the finding that alternative expressions for the same thing coexist in varying proportions in different speaker generations. When there is a change in progress, incoming and outgoing variants are both found in the speech community, but younger speakers typically show higher frequencies of the incoming form and older speakers lower. Analyzing the frequencies of the variants from different age-groups reveals the spread of the incoming variant, which can be depicted by an S-curve (see below).

Often changes are slower than can be measured using the apparent-time model. The basically probabilistic nature of linguistic variation and the gradualness of change can be captured when the linguistic variable is plotted diachronically against the external variable of real time. Figure 1 presents the replacement of the traditional subject pronoun *ye* by the object form *you* in 16th-century English. The data come from the *Corpus of Early English Correspondence*. The historical subject form *ye* prevails until the 15th century, but *you* is already attested in the data. It begins to spread in the first half of the 16th century, and the process accelerates in the second half, reaching completion at the beginning of the 17th century, when *you* has replaced *ye* in the material. The process forms an S-curve across time. The probabilistic nature of linguistic variation prevails, however marginally, even with completed changes such as this one, as the earlier form continues to occur in archaic contexts such as the Christmas carol 'Oh, come all *ye* faithful.'

Figure 1 Replacement of subject *ye* by *you*. Frequency of *you* between 1410 and 1620. Adapted from Nevalainen and Raumolin-Brunberg (2003: 60) with permission.

Many Factors Govern Linguistic Variation

Being probabilistic, a linguistic variable may be sensitive to a whole range of other variables, linguistic and social, each exerting a different degree of influence on how it is realized. The (ing) variable is typically represented by the alveolar [n] in the speech of working-class groups but frequently by the velar [ŋ] in the speech of middle-class groups, for instance, in Trudgill's Norwich study (1974). The alveolar variant is favored in casual speech and the velar one in formal styles. Similarly with linguistic factors, [n] is more common when (ing) is a verbal suffix, but [ŋ] tends to persist when it is part of a noun, as in *icing* or *ceiling*. Sociolinguists make use of multivariate statistical tools such as VARBRUL to measure the varying impacts of social, stylistic, and linguistic factors such as these on the choice of variant forms.

Differences in sensitivity to other factors can also be seen when a linguistic variable is not stable but is undergoing change: the process is completed by certain groups of speakers and in certain contexts earlier than in others. This process could be visualized by tracing the change in each context separately. Figure 2 illustrates how the final nasal was progressively lost in the English determiners *mine* and *thine*, which were shortened to *my* and *thy* between the 14th and the 17th centuries. The change was first completed in contexts where the determiner preceded a noun beginning with a consonant; next came nouns beginning with <h>, and

Figure 2 Replacement of *mine/thine* by *my/thy*. Frequency of *my/thy* in four contexts between 1410 and 1681. Adapted from Nevalainen and Raumolin-Brunberg (2003: 62) with permission.

then vowel-initial nouns. *Mine* and *thine* prevailed longest before *own*.

Linguistic Variables Are Socially Unique

Linguistic variables are sensitive to other factors, both linguistic and social, in different ways, which make them socially unique. The social profiles of linguistic variables are unique in that no two variables are exactly identical in terms of their linguistic and social embedding. There are a large number of factors that can pattern with people's linguistic choices. They range from the speaker's domicile, gender, age, and ethnicity to their socioeconomic class and social-group memberships and to style and register.

Frequent use of a particular linguistic form may be indicative, say, of social class in one speech community but not necessarily in another. This is the case of the English (r) variable, the pronunciation of postvocalic /r/ in words like *fourth* and *floor*. It is pronounced in most varieties of American English, but variation prevails, for instance, in New York City, where (r) is usually pronounced by higher status groups but less frequently by lower. This does not, however, mean that socioeconomic status is not a relevant variable in /r/-pronouncing communities. The distinction between higher and lower status groups can be indicated by other linguistic variables, such as (ing) and multiple negation (as in *I don't want nothing*).

The relevant social factors themselves can also be expected to vary from one speech community to the next, and combine in different ways. Distinctions based on region, for instance, are marked in the English spoken in England but less clear-cut in Australia. In practice, the social and pragmatic details of actual variation may be impossible to capture in fine detail, but the general point about the social uniqueness of linguistic variables emerges even with a limited number of social factors and also characterizes processes of language change. Moreover, there is no predictable connection between the outcome of a linguistic change and the scatter of social factors determining its course.

This generalization basically also applies to linguistic changes that diffuse from their region of origin across the language community. The use of *you* as a subject form started to spread from London in the 16th century, and it was promoted by the City and the Royal Court alike. In contrast, the short determiners *my* and *thy* spread from the north of England, and when they reached the capital they first gained ground among the merchants in the City of London, but took more time to make their way to the Court. These two examples illustrate differences in the regional and social embedding of two changes whose time courses partly coincided, although the diachronic trajectory of *my* and *thy* was less steep than that of *you*. That their histories are unique is also accentuated by the fact that their diffusion has been traced in personal letters produced by the same sets of informants: people and groups of people participated in ongoing changes to different degrees in the past, just as they do today.

Linguistic Variation Shows Gender Differences

The notion of social uniqueness applies to the combination of social factors associated with linguistic variables. It does not imply that certain individual factors could not have a similar effect on language variation and change at the macro level. The sex (or, in social terms, gender) of the speaker has often been found to account for linguistic variation better than social class. Gender differences are linked with linguistic prestige in numerous studies across languages as diverse as Arabic, Canadian French, Finnish, Persian, Spanish, and Mandarin Chinese. For stable linguistic variables that vary according to social class – such as (ing) and multiple negation in English – these studies show that women regardless of age and social status favor standard or supralocal forms, whereas men typically display higher frequencies of nonstandard or local forms. For this generalization to apply, however, both sexes must have access to the same linguistic repertoires: if women do not have the same educational opportunities as men, they cannot acquire the same prestige forms.

Gender differentiation also emerges diachronically, in language change. It is typically the case that women more readily than men promote incoming forms if these forms are associated with the standard or a wider, supralocal usage. Men, by contrast, tend to retain local forms (and therefore make good informants on local or regional usage). The innovative role of women in language change appears, for instance, in New Zealand English, where the success of phonological innovations, both prestige and vernacular, has been attributed to their first being adopted and endorsed by women. Taking an example from a non-Indo-European language, predictable gender differences also emerge in the morphophonemic changes that have been in progress over the last few decades at Virrat, a small rural town in Finland: women led all eight changes studied tending toward the norms of standard Finnish.

Similarly, women proved to be the leaders of 11 out of the 14 historical changes investigated in Renaissance English. The changes were all processes of supralocalization, and included the rise of the subject form *you* and the short determiners *my* and *thy* discussed above. However, they also included the

disappearance of multiple negation, that is, the replacement in negative clauses of combinations such as *not* … *no/never* by *not* … *any/ever*. In personal letters, this process could be traced back to the 16th century, and it was systematically led by men. At the time, women did not have the same opportunities for formal education as men, and for this reason could not spearhead changes that had their origins in formal registers of language use. Women emerged as the leaders of those changes that took place outside learned or professional language use, and so were instrumental in shaping the supralocal vernacular of their time.

Some of the patterns of discourse variation detected in modern synchronic research have also been replicated for the past. This is the case of markers of personal involvement such as first- and second-person pronouns, modal auxiliaries, and first-person evidential verbs (*assume*, *believe*, *doubt*, *find*, *guess*, *suppose*, *think*, etc.). Just as today, these features were used more frequently by women than by men in the 17th century. Women were found, for instance, to use *I think* more in all recipient categories investigated: when writing to their nuclear family members (parents, children, and spouses), to other family members, to close friends and to other, more distant recipients.

Variation Is Sensitive to Macro- and Micro-level Factors

Linguistic variables are susceptible not only to global factors such as the speaker's social class, age, gender, ethnicity, and geographical location but also to social networks and other local variables. Linguistic indexing of local social practices is an everyday experience. Institutional settings, for instance, may give rise to the formation of groups characterized by linguistic ingroup indicators. A study of an American high school identified two groups of students: those who had a positive attitude to school and its activities and those who actively dissociated themselves from school values. These group memberships were found to correlate with linguistic variation better than social class distinctions.

A number of social network analyses have been carried out, ranging from Australian Aboriginal adolescents and the inhabitants of an Austrian Alpine village to three working-class communities in Belfast and rural migrants to a Brazilian city; from British black adolescents and an island community in French West Indies to inner-city Detroit African-Americans and Melanesians in New Caledonia. A person's social network represents the sum total of the relationships he or she has contracted with other people. Some predictions can be made on the basis of social network structures concerning linguistic variation. Loose-knit networks, arising from contacts people contract with a variety of individuals, promote linguistic diversity and facilitate change. Language maintenance, in contrast, is fostered by networks in which people have many contacts with the same individuals in their different capacities, for instance, as neighbors and workmates.

Close-knit networks are easier to reconstruct for the past than loose-knit ones, where much of the necessary ethnographic information may not be available. A historical example of a close-knit network is the late 10th century Winchester School, a monastic community, which exerted a direct impact on Old English religious vocabulary. A case in point is also the *Spectator* magazine circle centered around Joseph Addison, which set a model for prose style in early 18th-century England.

Loose-knit social networks contribute to cities being typically the centers from which linguistic features diffuse to other localities. This is the case today with phonological variables such as the Northern Cities Shift, a series of related vowel changes associated with urban speech in the northern United States. In England the merger of initial fricatives such as /θ/ and /f/ in *thin* and *fin* has spread from London to other cities. It has been recorded in Norwich in East Anglia, in Sheffield, Derby, and Middlesbrough in the north of England, and even in Glasgow in Scotland.

The historical role of cities as centers of linguistic innovation and dialect leveling is also well documented. Most changes that have been studied empirically and that spread throughout England in the Renaissance period were promoted either by the City of London, the Royal Court or by both, or were given new impetus for their supralocalization by the capital. Paris displays a similar trend. Dialect leveling took place in the French capital early on due to immigration and dialect contact, and the élites sought to distinguish their language from that of the lower ranks. Parisian French started to make its way to other parts of France in the late Middle Ages. In Japan, the dominant center of political and cultural influence shifted from the Kyoto region in the west to Edo (present-day Tokyo) in the east in the 17th century, and the focus of linguistic prestige shifted accordingly. Modern Tokyo continued as the center from which standard literary forms spread to the rest of country.

Reflecting urban mobility and weak network ties, linguistic innovations can easily travel from one urban center to another. Uvular /r/ is reported to have jumped even across language boundaries in western Europe. In France it is traced back to the Royal Court in the 17th century, from which it moved to such urban centers as Bordeaux, Marseille, and Toulouse, but also found its way to the Dutch spoken in the Hague, to the German spoken in Cologne and Berlin, to Danish in

Copenhagen and Norwegian in Bergen. It reached Copenhagen in the late 18th century and the south of Sweden at the end of the 19th century. Innovations like this can bypass the countryside between urban centers: apical /r/ is still found in French regional dialects in the speech of the oldest generation.

The Principle of Contingency

One of the major findings of modern sociolinguists is that each linguistic variable is in principle socially unique. Whatever the speakers' motives that give rise to synchronic variation are, this variation provides the prerequisite for language change. It follows from these premises that linguistic changes have no single path of transmission but can pattern differently even with respect to the same social factors. This indeterminacy also extends to the relationship between linguistic and social factors in language change: "Factors determining the course of linguistic change are drawn from a pattern of social behavior that is not linked in any predictable way to the linguistic outcome" (Labov, 2001: 503). Put differently, Labov's Principle of Contingency states that the linguistic details of changes in progress are basically independent of their social embedding.

Syncretism

M Baerman, University of Surrey, Surrey, UK

© 2006 Elsevier Ltd. All rights reserved.

Definition

The term **syncretism** refers to the situation where a single inflectional form corresponds to multiple morphosyntactic feature values. The Old Irish noun paradigm in **Table 1** illustrates some representative instances.

Old Irish distinguishes five values for case (nominative, accusative, genitive, dative, vocative) and three values for number (singular, dual, plural). Multiplying out the logical possibilities yields a grid of 15 case-number distinctions (NOM SG, ACC SG, etc.). However, because of syncretism in the paradigm, there are only five distinct forms: *fer*, *firu*, *feraib*, *fir*, and *fiur*. There is syncretism of case (ACC/VOC PL *firu*), of number (DU/PL DAT *feraib*), as well as forms which combine different case and number values (*fir* serves for GEN SG and NOM PL, *fer* serves for NOM/ACC/VOC SG, ACC/GEN/VOC DU, and GEN PL).

In practice, most observers require some language-internal evidence that a particular morphosyntactic distinction is morphologically relevant in order to identify syncretism. For example, a value which is syncretic in one morphosyntactic context may be distinct in another, as with nominative and accusative in Old Irish, which are syncretic in the singular and dual but not in the plural. Or they may be syncretic in one lexeme but not in another; thus, nominative and accusative are syncretic in the singular of *fer*, but distinct for some other Old Irish nouns, e.g., *tuath* 'nation.NOM.SG,' *tuaith* 'nation.ACC.SG.'

Table 1 Declension of Old Irish 'man'

	SG	*DU*	*PL*
NOM	fer	fer	fir
ACC	fer	fer	firu
GEN	fir	fer	fer
DAT	fiur	feraib	feraib
VOC	fir	fer	firu

The significance of syncretism lies in what it can tell us about the structure of morphosyntax and morphology. If one holds that identity of form is a reflection of identity of function, then syncretism provides evidence for otherwise hidden aspects of feature structure. For example, the fact that dual and plural are collapsed in the form *feraib* might be used to show the relevance of a number value 'nonsingular,' which is in turn subdivided into dual and plural. On the other hand, some syncretic patterns involve the collapse of functionally incongruent values (e.g., GEN SG and NOM PL *fir*), and may be used to argue that morphological structure is independent of morphosyntactic structure.

Development of the Notion

The term *syncretism* applied to language first turns up in August Pott's (1836) *Etymologische Forschungen auf dem Gebiete der Indo–Germanischen Sprachen* [Etymological investigations on Indo–Germanic languages], where it is used in both a synchronic sense (as outlined above) and a diachronic sense, i.e., where originally distinct inflectional forms have fallen together over time. In the course of the 19th century, syncretism was largely treated as a diachronic problem, culminating in Delbrück's (1907) study of case syncretism in the Germanic languages. In the 20th century, the synchronic dimension came to the fore, starting with Jakobson (1936) and Hjelmslev (1935–1937), who developed the idea that syncretism could be used to explore the inner workings of morphosyntactic features. Syncretism continues to play a significant role in the construction of contemporary models of morphology, such as Network Morphology (Evans *et al.*, 2001), Paradigm Function Morphology (Stump, 2001), and Distributed Morphology (Noyer, 1997).

Typology

Although syncretism might be seen as deviation, a violation of a straightforward mapping of grammatical function onto morphological form, it is nevertheless endemic in inflectional systems. It is prob ably fair to say that, if a language has inflectional

Definition

The term **syncretism** refers to the situation where a single inflectional form corresponds to multiple morphosyntactic feature values. The Old Irish noun paradigm in Table 1 illustrates some representative instances.

Old Irish distinguishes five values for case (nominative, accusative, genitive, dative, vocative) and three values for number (singular, dual, plural). Multiplying out the logical possibilities yields a grid of 15 case-number distinctions (NOM SG, ACC SG, etc.). However, because of syncretism in the paradigm, there are only five distinct forms: *fer*, *firu*, *feraib*, *fir*, and *fiur*. There is syncretism of case (ACC/VOC PL *firu*), of number (DU/PL DAT *feraib*), as well as forms which combine different case and number values (*fir* serves for GEN SG and NOM PL, *fer* serves for NOM/ACC/VOC SG, ACC/GEN/VOC DU, and GEN PL).

In practice, most observers require some language-internal evidence that a particular morphosyntactic distinction is morphologically relevant in order to identify syncretism. For example, a value which is syncretic in one morphosyntactic context may be distinct in another, as with nominative and accusative in Old Irish, which are syncretic in the singular and dual but not in the plural. Or they may be syncretic in one lexeme but not in another; thus, nominative and accusative are syncretic in the singular of *fer*, but distinct for some other Old Irish nouns, e.g., *tuath* 'nation.NOM.SG,' *tuaith* 'nation.ACC.SG.'

Table 1 Declension of Old Irish 'man'

	SG	*DU*	*PL*
NOM	fer	fer	fir
ACC	fer	fer	firu
GEN	fir	fer	fer
DAT	fiur	feraib	feraib
VOC	fir	fer	firu

The significance of syncretism lies in what it can tell us about the structure of morphosyntax and morphology. If one holds that identity of form is a reflection of identity of function, then syncretism provides evidence for otherwise hidden aspects of feature structure. For example, the fact that dual and plural are collapsed in the form *feraib* might be used to show the relevance of a number value 'nonsingular,' which is in turn subdivided into dual and plural. On the other hand, some syncretic patterns involve the collapse of functionally incongruent values (e.g., GEN SG and NOM PL *fir*), and may be used to argue that morphological structure is independent of morphosyntactic structure.

Development of the Notion

The term *syncretism* applied to language first turns up in August Pott's (1836) *Etymologische Forschungen auf dem Gebiete der Indo–Germanischen Sprachen* [Etymological investigations on Indo–Germanic languages], where it is used in both a synchronic sense (as outlined above) and a diachronic sense, i.e., where originally distinct inflectional forms have fallen together over time. In the course of the 19th century, syncretism was largely treated as a diachronic problem, culminating in Delbrück's (1907) study of case syncretism in the Germanic languages. In the 20th century, the synchronic dimension came to the fore, starting with Jakobson (1936) and Hjelmslev (1935–1937), who developed the idea that syncretism could be used to explore the inner workings of morphosyntactic features. Syncretism continues to play a significant role in the construction of contemporary models of morphology, such as Network Morphology (Evans *et al.*, 2001), Paradigm Function Morphology (Stump, 2001), and Distributed Morphology (Noyer, 1997).

Typology

Although syncretism might be seen as deviation, a violation of a straightforward mapping of grammatical function onto morphological form, it is nevertheless endemic in inflectional systems. It is prob ably fair to say that, if a language has inflectional

Table 2 Third person possessive pronoun in Laal (Boyeldieu, 1982: 14)

	SG	*PL*
MASC	ðā:r	ðè:rí
FEM	ðò:g	ðè:rí
NEUT	ðà:ná	ðuà:ná

FEM	ye-	kni-	wati-, węn-
NEUT	ka-, w-, y-	kni-	wati-, węn-

morphology, it is likely to display syncretism. The most commonly affected features, crosslinguistically, are case, person, gender, and number.

Case syncretism most typically affects the core cases used to express subject and object. One pattern involves collapse of core case distinctions, as in the nominative/accusative syncretism of Indo–European neuters (compare the neuter form of the Latin adjective 'good,' *bonum*, which combines nominative and accusative, with the masculine, which has a separate form for nominative, *bonus*, and for accusative, *bonum*). The same pattern may also occur in ergative ~ absolutive systems. For example, in the Daghestanian language Tsakhur (Kibrik, 1999), pronouns have absolutive/ergative syncretism (e.g., *zɨ* 'I.ERG/ABS'), while nouns maintain distinct forms for these two cases (e.g., *baIčar* 'idiot.ABS,' *baIčar-ē* 'idiot.ERG').

Cross-linguistically, there is often a correlation with animacy: high animacy arguments favor maintenance of a distinct object case form, while low animacy arguments favor a distinct agent case form. (Animacy here is broadly construed, with number, word class, person, and specificity also playing a role.) Both these tendencies are manifested in so-called split ergative languages. The other major pattern of case syncretism involves the collapse of one of the core cases (typically accusative or ergative) with some noncore case, as in the well-known accusative/genitive of the Slavic languages (e.g., Russian *eë* 'her.ACC/GEN' vs. *žen-u* 'wife-ACC,' *žen-y* 'wife-GEN') or the ergative of the Chukotko–Kamchatkan language Koryak (Žukova, 1972), which is syncretic with the locative for nouns which denote specific human individuals (*anjana-k* 'grandmother-ERG/LOC' vs *anja-ta* 'a grandmother-ERG,' *anja-k* 'a grandmother-LOC'). Finally, case syncretism between non-core cases is also found (especially in Indo–European languages), but the patterns tend to be language-specific, in keeping with the varied repertory of noncore cases cross-linguistically.

Syncretism of person most often affects nonsingular values, typically combining first and second or second and third person. For example, the Chibchan language Ika (Frank, 1990) has 1PL/2PL syncretism (e.g., *a-tšuana* 'we/you.PL saw'), while the Papuan (Trans-New Guinea phylum) language Amele (Roberts, 1987) has 2PL/3PL syncretism (e.g., *feigan* 'you.PL/they saw'). Where verbs mark both subject and object, one often finds the collapse of subject person distinctions in the presence of certain object values. For example, in the Papuan (Sepik–Ramu family) language Yimas (Foley, 1986), second and third person singular subject are distinct in intransitive verbs, but syncretic in transitive verbs with a third person object, e.g., *nan-tayŋcut* 'you.SG/he see(s) him' versus *ma-wat* 'you.SG want,' *na-wat* 'he wants.'

Gender syncretism shows a decided tendency to affect nonsingular values. For example, in Laal, an unclassified language of Chad (Table 2), masculine and neuter are syncretic in the plural; in the Iroquoian language Seneca (Table 3), feminine and neuter are syncretic in the plural; and in the Nilotic language Turkana (Table 4), masculine and neuter are syncretic in the dual and plural (the alternative forms are for [±RESTRICTIVE], a feature akin to definiteness).

Number syncretism shows a decided tendency to unite nonsingular values. For example, in the Australian language Bininj Gunwok (Gunwinyguan family; Evans, 2003), pronominal prefixes regularly distinguish three number values, while free pronouns distinguish only two: compare the subject prefixes *ngi-* '2SG,' *nguni-* '2DU,' *ngurri-* '2PL' with the free pronouns *ngudda* '2SG' and *wudda* '2DU/PL.'

It should be noted, however, that purely language-specific patterns of syncretism are also common. In part, these can be traced to the morphologization of originally accidental patterns of homophony. For example, Kuryłowicz (1949) attributes the syncretism of second and third person singular in the Old Scandinavian present tense indicative verb conjugation to the analogical extension of a pattern that originally appeared in one class of verbs as the result of regular sound change.

Formal Issues

To describe syncretism in a morphological analysis, two approaches are possible, underspecification and stipulation.

With underspecification, the morphological exponent is undefined for some feature, and so is compatible with multiple values of that feature. Consider

Table 4 Gender–number prefixes in Turkana (Dimmendaal, 1983: 217) (restricted, unrestricted)

	SG	PL
MASC	e-, lo-	ŋi-, lu-
FEM	a-, na-	ŋa-, na-
NEUT	i-, ni-	ŋi-, lu-

Table 5 Latin second declension (singular)

	Masculine 'slave'	*Neuter 'war'*	*Neuter 'crowd'*
NOM SG	serv-us	bell-um	vulg-us
ACC SG	serv-um	bell-um	vulg-us
GEN SG	serv-ī	bell-ī	vulg-ī
DAT/ABL SG	serv-ōō	bell-ōō	vulg-ōō

gender syncretism, as illustrated in Table 2, Table 3, and Table 4. We might treat gender as a composite of two subfeatures, [±HUMAN] and [±MASC], where masculine = [+HUMAN, +MASC], feminine = [+ HUMAN, −MASC], and neuter = [−HUMAN, −MASC]. The masculine/feminine syncretism seen in Laal could thus be described by saying that the form *δè:rí* is underspecified for [±MASC]. In this use of underspecification, syncretism is a direct mirror of the natural class represented by [+HUMAN]. Alternatively, underspecification can be used to generate 'elsewhere' forms. For example, the masculine/neuter syncretism of Turkana might be described by saying that the prefixes *ŋi-* and *lu-* are underspecified for both [±HUMAN] and [±MASC], while the prefixes *ŋa-* and *na-* are fully specified as [+HUMAN, −MASC]. In this approach, *ŋi-* and *lu-* are simply default plural prefixes used to fill out the undefined portions of the paradigm; the fact that they combine specifically the values masculine and neuter is of no significance.

With underspecification, syncretic patterns are not directly defined by morphology, but are rather a by product of natural classes of morphosyntactic values. In a model of grammar where morphology plays only a limited role, this is a desirable outcome. However, there is some evidence that the complexity of syncretic patterns may be too great to rely solely on underspecification, suggesting that at least some types of syncretism are best described through morphological stipulation. The main challenges posed to underspecification come from two phenomena.

First, there are instances of syncretism for which no plausible natural class of morphosyntactic values could be assumed. For example, in the Cushitic language Dhaasanac (Tosco, 2001), the person–number–gender paradigm of verbs displays a maximum of two forms, one for 1SG/1INCL PL//3SG MASC/3PL and one for 2SG/2PL/3SG FEM/1PL. This opposition is morphologically systematic, as is shown by the variety of ways in which it is manifested (consonant or vowel alternation, suffixation, prefixation), depending on tense-mood and on the lexeme itself, e.g., *leeði* ~ *leeti* 'fall down.PERF,' *seð* ~ *sieti* 'walk. PERF,' *ʔuufumi* ~ *ʔuufeeni* 'cough. PERF,' *yes* ~ *ces* 'kill.PERF.' Each form combines disparate morphosyntactic values, which cannot be reduced to any obvious natural class. While it might be possible to treat one of these as an 'elsewhere' form, the combination of values found in the other form must still be accounted for.

Second, some examples show evidence of an internal asymmetry, that is, the syncretic form looks as if it is really the exponent of one of the component values. In some of these cases, underspecification is insufficient as a descriptive mechanism. Consider the singular paradigm of second declension Latin nouns in Table 5. Masculines have a distinct nominative in *-us* and accusative in *-um* while neuters have nominative/accusative syncretism, typically with the ending *-um*, though some nouns have *-us*. Thus, the syncretic nominative/accusative of neuters looks like the accusative (*-um*) for some nouns and like the nominative (*-us*) for others. The distribution of forms across the three paradigm types does not lend itself to analysis in terms of underspecification, since *-um* and *-us* would need sometimes to be underspecified for the distinction between accusative and nominative, and sometimes be specified distinctly as accusative or nominative.

Such examples appear to require morphological devices in addition to underspecification. The first suggests the need for stipulated classes of morphological values, i.e., there is an overt rule which states that certain distinct values are grouped together ('morphomes' in the sense of Aronoff, 1994). The second example suggests the need for rules of referral, which state that the form for one value is the same as the form for another value, e.g., that the accusative takes the form of the nominative in nouns of the *virus* type. The existence of such stipulated morphological devices does not invalidate the notion of underspecification, but rather supplements it, and provides some evidence for the autonomy of morphology.

Synesthesia

C M Bretones Callejas, University of Almeria, Almeria, Spain

© 2006 Elsevier Ltd. All rights reserved.

Synesthesia (also spelled synaesthesia), from Greek *syn* ('with') and *aesthesis* ('sensation'), means 'the union of senses' and has the same root as the word *anesthesia* 'without the use of the senses.' It has been widely established that synesthesia occurs when an individual receives a stimulus in one sensory modality and experiences a sensation in another. However, synesthesia usually occurs within the same modality, e.g., color-grapheme synesthesia wherein individuals perceive colors when presented with achromatic digits or letters (Baron-Cohen *et al.*, 1993; Elias *et al.*, 2003). Thus, we could say that synesthesia takes place when ordinary stimuli elicit extraordinary conscious experiences.

Throughout history efforts have been made to make sense of the phenomenon behind the term by such as Pythagoras, Plato, or Aristotle, and later by Baudelaire, Rimbaud, Rimsky-Korsakov, Scriabin, Kandinsky, Nabokov, Einstein, Messiaen, Hockney, Feynman, and so on (van Campen, 1997; Ione and Tyler, 2004). However, synesthesia has been interpreted in many different ways (Galeyev, 1999). It was consigned to abnormality, philosophy, or metaphor for centuries; but on the other hand was recognized as a physiological fact because for some individuals, certain stimuli cause synesthetic responses or synesthetic perception. The challenge is to find at what level synesthesia is taking place: as (1) intersensorial connections or bonds in the psyche when used to describe the result of its manifestations in specific fields such as arts; or as (2) phonetic tropes and stylistic figures, relative to semantic intersensorial transfers. But these two levels are deeply linked, showing proof of the inseparability of categories, concepts, and experience (Lakoff and Johnson, 1999).

As a rhetorical figure, synesthesia consists in giving something a quality it cannot have: e.g., the parts of *white voices* are perceived by different senses. In the case of literary synesthesia, three types of study have been considered (Erzsébet, 1974):

- The analysis of sensorial combinations in the rhetoric of a single poet, within the framework of characterization of his/her individual style. For example, works on Oscar Wilde by Ullmann, on Heine by Silz, on Baudelaire by Roeding, on Montale by Rosiello, and on Ungaretti by Gutia.
- The study of synesthesia finds parallels in the style of different poets. For example, in the work on Keats and Byron by Ullmann, or on Eminescu, Arghezi, and Sadovaenu by Mancas.
- The elaboration of a comprehensive view about the synesthetic characteristic of a literary school or a certain period: The Renaissance and Baroque, or Romanticism, for instance.

In the linguistic interpretation of synesthesia, we must distinguish both the psycho-physiological process and its linguistic projection.

Synesthesia in Thought

The study of synesthesia could be divided in two general groups that overlap. First, synesthesia proper, i.e., when the stimulus of a sensorial input induces sensation in a different sensory module. Second, cognitive or categorial synesthesia entails synesthetic addition to the categorial systems of each individual or culture. Thus, synesthesia makes an interesting topic of investigation in that the subject matter is an internal, mental state whose existence we can infer from the findings of behavioral testing. But the growing interest in synesthesia has led to numerous experimental studies that rely upon self-reports given by subjects with synesthesia, and upon objective quantification of data gathered under traditional methods of experimental psychology or neuroscience. Varying criteria have been applied to the diagnosis of synesthesia, although in general, scientists have always differentiated clinical synesthesia from metaphor, literary tropes, sound symbolism, and deliberate artistic contrivances that employ the term to describe multisensory joinings.

Synesthesia proper has defined neurological components (Cytowick, 1993, 2002; Lovelace *et al.*, 1999; Grossenbacher *et al.*, 2001) and is believed to pass on genetically through X-chromosomes (Cytowic, 1995; Harrison, 2001). The percentage of synesthetic human beings varies according to the kind of synesthesia we are referring to (Day, 1996, 2004). It is estimated that we can find one "basic (cognitive) synesthete" (who perceives e.g., colored letters) in every 500 people; one "proper synesthete" (who perceives e.g., colored musical sounds or colored tastes) in 3000; and one "multiple synesthete" (multiple synesthetic experiences) in 15 000. It is possible that more than half of the human race are "basic synesthetes" that consider high sounds as bright and low sounds as dark (Day, 1996). And it might be possible that all human beings are synesthetic at

birth (Baron-Cohen and Harrison, 1996; Harrison, 2001).

Cytowic (1995) proposed five criteria for the diagnosis of a type of clinical synesthesia called ideopathic or developmental synesthesia as opposed to acquired forms of clinical synesthesia such as drug-induced synesthesia, epileptic synesthesia, and synesthesia due to acquired brain lesions:

- Synesthesia is involuntary but elicited.
- Synesthesia is projected. If visual, a photism will appear outside the body in the region close to the face.
- Synesthetic percepts are durable and discrete. The associations for an individual synesthete are stable over his/her lifetime: if a sound is blue, it will always be blue.
- Synesthetic experience is memorable. Many synesthetes exhibit hypermnesia (prodigious memory).
- Synesthesia is emotional in nature. A synesthetic experience is accompanied by a sense of noetic certitude.

Synesthesia is a conscious experience of systematically induced sensory attributes that are not experienced by most people under comparable conditions (only by synesthetes). It is considered by many as a normal brain process that is prematurely displayed to consciousness in a minority of individuals. At the other extreme, we find Merleau-Ponty's belief (1962) that synesthetic perception is something that we unlearn (probably through a pruning effect), though we are unaware of it because scientific knowledge shifts the center of gravity of experience so that we unlearn how to see, hear, and generally speaking, feel. Ramachandran and Hubbard (2001) saw synesthesia as a window into perception, thought, and language. Rich and Mattingley (2002) showed that synesthesia has been considered a reaction to physical stimulus, but they also prove that it can be activated with the mere thought of a particular stimulus or concept.

Within cognitive synesthesia, certain groups of things that our individual cultures teach us to set together or categorize in certain way, or specific conceptual structure – such as letters, numbers, or the names of persons – also have some kind of sensorial addition, such as a smell, a color, or a flavor. The most common forms of cognitive synesthesia entail elements such as characters written in color, numbers, time units, and musical notes or chords. For example, a person could perceive different colors with different spoken vowels or consonant sounds.

The pairings between eliciting stimuli and the resulting synesthetic experiences differ widely between synesthetes. For any given synesthete, there appears to be high consistency of the pairings over time (Baron-Cohen *et al.*, 1987, 1993; Odgaard *et al.*, 1999; Dixon *et al.*, 2000; Lyons, 2000; Mattingley *et al.*, 2001). But many brain studies locate this phenomenon in distinct areas of the brain (Cytowic, 2002). Functional imaging studies have shown that areas within the ventral pathway that normally register shape, color, and words are activated in synesthetes, but in addition, there is also parietal activity, which for the most part has been downplayed (Robertson, 2003). Some have argued that the automaticity and consistency of the synesthetic experience represent direct connections between cortical feature maps, perhaps through synaptic connections that fail to undergo normal synaptic pruning during development. This explanation of synesthesia is consistent with findings from a number of behavioral experiments suggesting that synesthetic binding precedes attention (Robertson, 2003).

Synesthesia in Language

The opinions of linguists concerning the concept of synesthesia can be contradictory:

1. Taking interest in the acoustic synesthesia, conferring sensorial properties to the sounds of speech, to the names of the days and the months and so on (Slawson, 1968, 1985).
2. The sphere of synesthesia is limited only to sensorial fields, e.g., *white stillness, velvet warmth*. This sphere can be widened to the sensorial combinations proper, but also the associations between abstract notion and a sensory impression, e.g., *sweet desire, blue slyness* (Erzsébet, 1974).
3. In synesthesia, semantically incompatible components are subordinated to a common dominant notion of the sensorial field, containing combinations of different sensations of elements belonging to the same sensorial field, e.g., the oxymoronic *blind light, dumb song* (Erzsébet, 1974).

Some consider that if the elements of the combination are semantically compatible, as in *silent night, the rustle of the red poppy*, we cannot speak about 'synesthesia' – which is a syntactic relation between semantically incompatible elements, denoting sensations from different sensorial spheres (Ward and Simner, 2003). According to a widespread view, synesthesia results from semantic transfer of a feature based on the similarity of two concepts. Some consider it completely subordinated to metaphor. Others postulate that it is produced by the transfer of the name based on simultaneous contiguity of the sensations, thus pointing out the relationship of

synesthesia with metonymy. Different researchers propose different models of this intersensorial phenomenon. Some take a diachronic perspective such as Williams (1976), Classen (1993) or Evans and Wilkins (2000), and others a synchronic perspective e.g., Ullmann (1964), Day (1996), Cacciari (1998), or Bretones (2001).

In Ullmann's view, synesthesia is at the borderline between the category of direct name-transfer based on synesthetic similarity and the association of a concrete sensation with an abstract notion; name-transfer based on simultaneous sense-contiguity. Ullmann (1964) claimed the possibility of a basic pattern of activation for synesthesia:

> [F]urther investigations might also reveal that the movement of synaesthetic metaphors is not haphazard but conforms to a basic pattern. I have collected data for the sources and destinations of such images in a dozen nineteenth-century poets, French, English and American, and have found three tendencies which stood out very clearly: (1) transfers from the lower to the more differentiated senses were more frequent than those in the opposite direction: over 80 per cent of a total of 2000 examples showed this 'upward' trend; (2) touch was in each case the largest single source, and (3) sound the largest recipient. (Ullmann, 1964: 86).

Less differentiated senses would be smell and taste, and the most differentiated ones hearing and vision. Ullmann proposed the following model of synesthesia:

smell/taste → hearing/vision → touch

This model is followed by Day (1996), but others disagree with his ranking (Cacciari, 1998; Bretones, 2001). Classen (1993), in a study fundamentally based on observations, determines the following synesthesic-metaphoric rank in English:

hearing → vision → smell → taste → touch

Day investigated this pattern and tried to determine the synesthetic metaphors used in English through corpus analysis (1996) and the study of human subjects (2004). He obtained data from the language in written texts and electronic sources such as The World Library's Greatest Books Collection, The Oxford Text Archive, and Project Gutenberg (Day, 1996). Using the percentages of concurrence of each synesthetic metaphor, Day (1996: 8) obtained the following pattern:

hearing
→ vision → smell → temperature → taste → touch

Synesthetic transfer is considered one of the most common types of metaphoric transfer – the transmission of information from one sensory modality to another (Williams, 1976: 463). Recent work on metaphor makes it clear that many of our most basic concepts (and our reasoning via those concepts) are **embodied**. Lived experiences in the body inspire and constrain the way we conceive and articulate many of our other experiences (Lakoff and Johnson, 1999; Bretones, 2001). "Metaphor, with its capacity to introduce a sensory logic at the semantic level is a way to fill this gap [...] since metaphors allude to a more complex scenario of interrelated meanings and experiences of the world" (Cacciari, 1998: 128).

One should not believe that all our knowledge about our sensory and perceptual experiences can be captured in a set of independent – or even interrelated – verbal categories; nor that sensory/perceptual experiences themselves reduce in any simple manner to a list of attributes. Still, the study of synesthetic metaphor may serve as a useful model (Marks, 1978). Being approachable through psychophysical analysis, synesthetic metaphors not only permit ready quantification, but enable us to assess development trends in the ways that at least certain aspects of such metaphors are interpreted. A psychophysics of synesthetic metaphor may eventually reveal much about perception and language (Marks, 1983, 2000). To appreciate the depth and extent of human metaphorical capacity will thus demand cognitive, psychological, and physiological analyses of phenomena such as synesthesia.

Synesthesia and Language

J Ward, University of London, London, UK
R Cytowic, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Sharing a Greek root with anesthesia, meaning 'no perception,' synesthesia (*syn* 'together' + *aisthēsis* 'perception') means 'joined perception,' wherein two or more senses are coupled such that a voice, for example, is not only heard but also felt, seen, tasted, or even sensed in multiple modalities. Individuals who undergo such automatic crossmodal perceptions are called 'synesthetes.' For a long time, synesthesia endured reflexive hostility from critics, who insisted it could not possibly be real, at best conceding the subjective experience as nothing more than a learned association or metaphoric speech. Doubts regarding its genuineness as a neurological phenomenon have been thoroughly answered.

Cytowic (1997, 2002a) elucidated general properties: synesthetic experience is involuntarily elicited, consistent, memorable, affect laden, perceptually simple, and spatial. Stroop interference confirms that synesthetic associations are automatic (Smilek and Dixon, 2002) whereas lawful segregations such as perceptual grouping, popout, and stereoptic fusion confirm their early perceptual nature (Ramachandran and Hubbard, 2001a; Palmeri *et al.*, 2002), and xenon, PET, and MRI methods have diversely shed light on the functional landscape of synesthetic experience. The phenomenon is more common than once believed, occurring in at least one in 2000 individuals by population prevalence estimate (Baron-Cohen *et al.*, 1996) and ten times as many by less sound surveys. Forty percent have more than one type of synesthesia (polymodal), and females predominate by more than three to one.

Despite an overall impression that synesthetic experiences are perceptual, some two-thirds of instances are actually triggered by hearing, reading, or thinking of letters, integers, or words (Table 1).

We first review evidence that graphemes and phonemes – the building blocks of language – can trigger synesthetic experiences of color and taste. Secondly, we consider the interplay between synesthesia and concept formation. We conclude that synesthesia is not a mere curiosity in a few brains, but widespread with broad implications and possible use as an experimental probe for understanding metaphor and language evolution.

Colored Graphemes

The naming convention of putting synesthetic sense before its stimulus yields the terms 'color-lexical,' 'color-graphemic,' and 'color-phonemic' synesthesia. Graphemic is the most common type, wherein letters, numerals and, less often, punctuation, Braille, and musical symbols automatically evoke color sensations; phonemes trigger just 10% of cases. Individuals characteristically describe colors in precise detail (e.g., 'dirty, dull yellow' or 'deepest violet with sparkles'). Colors remain consistent over years, whereas nonsynesthetes asked to generate letter–color associations are only about 30% consistent after an interval of a week. Consistency over time is the most commonly used measure of authenticity. An example of colored graphemes is shown in Figure 1.

Word colors are variously derived from constituent graphemes. In some, the first letter dominates, thus *psychology*, *photograph*, and *poetry* all share the same color as the letter P. Other synesthetes base word colors on consonant or vowel composition. A double dissociation exists between consonant and vowel influences on word color (Ward *et al.*, 2005), demonstrating how synesthesia can inform theories of language by suggesting, in this instance, that consonant–vowel coding may be an intrinsic property of graphemic representation (see also Ward and Romani, 2000).

Upper- and lower-case letters usually, but not always, evoke identical colors, whereas Arabic numerals are seen differently from Roman ones. Navon figures reveal attentional influences: for example, a black numeral 5 target composed of smaller 2s is seen

Table 1 Typological distribution

Graphemes → Color	68.8%
Time Units → Color	23.3%
Music Sounds → Color	19.2%
General Sounds → Color	14.0%
Musical Notes → Color	10.6%
Phonemes → Color	10.6%
Tastes → Color	7.1%
Smell → Color	6.9%
Pain → Color	6.3%
Sound → Taste	5.6%
Personalities → Color	4.8%
Touch → Color	3.9%
Temperatures → Color	2.7%
Vision → Taste	2.3%
Sound → Smell	1.6%
Vision → Sound	1.6%
Orgasms → Color	1.1%
Vision → Smell	1.1%
Vision → Touch	1.1%

A distribution of the types of synaesthesia based on 588 cases. Approximately 40% of individuals have multiple types of synaesthesia. For simplification, the table does not include types of synaesthesia affecting less than 1% of the sample.

Figure 1 An example of a synesthete's colored graphemes.

as green, say, when the subject attends to the global configuration, but as orange when attending to its constituent 2s. As each synesthete has idiosyncratic associations, experiments must be tailored to the individual; nonetheless, regularities do exist. Synesthesia is also observed for scripts that do not use the Roman alphabet (see e.g., Mills *et al.*, 2002).

Sir Francis Galton first noted synesthesia's strong heritability in 1883 (Baron-Cohen *et al.*, 1996) and contemporary evidence suggests that mammalian neonates, including humans, are born with synesthesialike responses (Maurer, 1997). Yet graphemes and words are cultural symbols acquired later in life. Because synesthesia takes on an extraordinary variety of forms, any general theory must account for it in terms of both neural development and acquired experience (e.g., of one's own particular language).

Gustatory Phonemes

One can only speculate about the relative rarity of synesthesia induced by phonemic patterns (Table 1). Grapheme recognition exists from about age 3 to 4 years (Frith, 1985). Possibly, color-graphemic synesthesia begins as color-phonemic and then undergoes conceptual reorganization according to accepted phoneme-to-grapheme conversion rules and literacy acquisition. There is no *a priori* reason why infant synesthetic brains should not undergo the same reorganization pressures as others. Prospectively testing this conjecture would be difficult but not impossible.

Subject JIW tastes flavors in his mouth whenever he hears, reads, speaks, or thinks about words (Ward and Simner, 2003). *Safety* tastes of "toast lightly buttered," *Phillip* tastes of "oranges not quite ripe." As with other types of synesthesia, his sensations are stable over time and he is significantly more consistent than controls asked to generate or memorize word–food associations. Detailed analysis of his word–taste associations shows that words containing common patterns of phonemes (rather than graphemes) tend to produce the same taste. For example, *marriage*, *village*, and *college* all contain a common phonemic rhyme and all elicit a taste of sausage sandwiches. In contrast to color-graphemic synesthetes, there is no relationship between the taste assigned to graphemes and that assigned to words, and words sharing the first letter tend not to produce the same taste.

Notably, not only do words with similar phonemes evoke similar tastes but also the phonemes tend to be present in the form of the word corresponding to that taste. Thus, *Sydney* tastes of kidney, *auction* tastes of Yorkshire Pudding, *super* tastes of tomato soup, and so on. It is as if the phonological forms of food-related vocabulary have served as a template for deriving synesthetic associations for other words. This again points to the need for better understanding of the interplay between innate and environmental factors. This trend is found for all other known cases, comprising three cases from the historical literature and seven published contemporary cases (see Ward *et al.*, 2005).

What biological reason could explain why graphemic properties preferentially elicit color whereas phonological ones elicit tastes? Ramachandran and Hubbard (2001a) proposed an 'adjacency theory.' In color-graphemic synesthesia, they emphasized that the grapheme recognition region on the left fusiform gyrus lies adjacent to area V4, which concerns color perception. Only left V4 activates in individuals who see color in response to spoken words (Nunn *et al.*, 2002). Synesthetes might plausibly cross-activate these regions because of either unusual projections or lack of inhibition between them. Others have similarly referred to the assumed cross-activation of grapheme and color regions in synesthetes as a breakdown of modularity (Baron-Cohen *et al.*, 1993) or as anomalous binding of modules (Cytowic, 2002b, 2003).

Figure 2 The higher the pitch and/or louder the sound the 'brighter' it is judged to be, and the lower the pitch and louder the sound the 'larger' it is judged to be.

The gustatory cortex is bilaterally located in the frontal and parietal opercula and the insula. This is certainly not adjacent to the grapheme recognition region on the left fusiform gyrus, perhaps explaining why graphemic properties of words have little influence on synesthetic tastes. Nor are the Wernicke phonemic regions any closer. Even though all sensory modalities and the visceral milieu are represented in the insula, which also responds to both speech perception and production (Wise *et al.*, 1999), adjacency alone appears inadequate as a general synesthetic mechanism. As the phonological associations derive from a single semantic category, 'food,' we may speculate on the necessary recruitment of additional brain areas (for example, anterior temporal regions supporting semantic memory). One inference follows that synesthesia does not localize to a discrete locus in the sense of classical neurology but rather is supported by a network of structures (Cytowic, 2002a, 2003).

Structure versus Meaning

We have so far concentrated on the internal structure of words – both graphemic and phonological. But what about meaning? Marks (1978) showed that systematic correspondences exist among dimensions of a given sense for synesthetes and nonsynesthetes alike. For example, both say that louder tones are brighter than soft tones, higher ones are smaller than lower ones, and that low tones are both larger and darker than high ones. The perceptual similarities that yield such orderly relationships among pitch, loudness, brightness, and size (Figure 2) can be described in psychophysical terms such as temporal coding or opponent processing, and may be rooted in fundamental similarities of phenomenal experience. For example, von Békésy (1959) first noted physiological similarities between hearing and touch.

Figure 3 A painting of two bars of music from a music-to-color synesthete.

Figure 3 is an illustrative painting of two bars of music from a synesthete, in which different shades, shapes and positions may correspond to different notes.

The demonstration of regular congruences between many (though not all) qualitative aspects of experience in different modalities has led to the idea of a continuum from perception → synesthesia → metaphor → abstract language, as perceptual similarities, synesthetic equivalences, and metaphoric identities in turn become available to the more abstract knowledge that is embodied in language (Cytowic, 2002b; Marks *et al.*, 1987; Ramachandran and Hubbard, 2001b). For example, a tone of 2000 Hz may be labeled 'high' pitched and one of 100 Hz labeled 'low' pitched. Why do we use a spatial metaphor for pitch? The pitch–space association is not strictly linguistic, because Stroop-like interference exists between pitch and space in perceptual judgment tasks (Bernstein and Edelstein, 1971) and infants are sensitive to this correspondence (Wagner *et al.*, 1981). In this instance, a basic crossmodal correspondence has entered into metaphorical language and has perhaps even influenced the development of Western musical

Figure 4 An example of spatial 'forms' for shoe sizes, height, weight, and body temperature, reprinted from Cytowic (2002a), MIT Press.

notation (increasing pitch associated with higher position on the stave).

An even stronger claim is that these correspondences could have provided an early protolanguage during human evolution (Cytowic, 2002b; Ramachandran and Hubbard, 2001b). Humans seem able to agree crossculturally upon the assignment of certain symbols to represent objects (see, e.g., Davis, 1961) or upon how one domain can be expressed in terms of another (e.g., colors and emotions; D'Andrade and Egan, 1974). Kohler (1947) presented participants with two shapes and asked them to decide which one was called 'takete' and which one was called 'maluma.' Participants tended to associate rounder visual forms with 'maluma,' and more angular forms with 'takete.' This trend appears to be crosscultural insofar as a group of people in Tanzania showed a similar associative bias.

Even though each synesthete's responses are idiosyncratic, their associations are not arbitrary. Although our understanding of this is incomplete, many researchers concur that the orderly topographic mapping characteristic of many cortical areas likely underlies this nonarbitrariness. Synesthetic associations may lay bare other properties of cognitive

Figure 5 A colored spatial form for months of the year.

representation that may not be immediately apparent to the nonsynesthete. This is considered in the final section below.

Semantic Categories as Synesthetic Inducers

Certain semantic categories may have a privileged status in synesthetic induction. Such categories include numbers and other ordinal representations (days, months, etc.), vocabulary used to denote perceptual categories (e.g., color words, food names), and names of familiar people, which may be imbued with color via their affective status to the perceiver.

The term 'number form' is somewhat of a misnomer given that the configurations concern not only integers, but any concept involving serial order. Thus, the perceptual qualities of spatial location, shape, and, often, color become synesthetically joined to semantically ordered sets such as integers, months, days, the alphabet, shoe sizes, temperature, and so forth (see Figures 4 and 5 for examples). Ordinality and configuration both suggest participation of the angular gyrus in this type of synesthesia. There is evidence that we all implicitly represent numbers in a visuospatial format: nonsynesthetes are faster at making judgments about small numbers (e.g., 1, 2) with their left and faster at making judgments about larger numbers (e.g., 8, 9) with their right hand (see, e.g., Dehaene *et al.*, 1993).

A special category for synesthetes experiencing color is color names – red, yellow, green, etc. Gray *et al.* (2002) report that some synesthetes cannot

inhibit a word's conceptual color. Thus, *red* may evoke a red synesthesia despite all other R words being green. In other cases, *red* may elicit a green synesthesia – a phenomenon the authors call the 'alien color effect.' It possibly arises from competition between different levels of representation (graphemic versus lexical-semantic) in the process of mapping synesthetic color.

Gustatory synesthetes presented with food names (e.g., *beef*, *cheese*) typically experience the appropriate sensation (e.g., the word *cheese* elicits a cheesy taste). There is little evidence for an 'alien taste effect' in which the word *cheese* would produce a taste of beef. Meaning appears more operative in gustatory than in color synesthesia, and although phonological factors influence synesthetic taste, the phonemic patterns themselves derive from the words used to represent the semantic category of food, as pointed out above.

Another special semantic category is people's names (Ward, 2004; Weiss *et al.*, 2001). GW experiences people's names as colored depending on whether she is personally familiar with anyone so christened. Using colors to describe people is a common feature of many natural languages (Asch, 1955). However, GW does so significantly more consistently than controls and shows Stroop-like interference when the names are printed in incongruous ink colors. Perhaps the emotional context determines both the presence of color and the particular color evoked by acquaintances. Indeed, GW reports synesthetic colors with other emotional words (e.g., hatred, marriage). This case again illustrates the interaction between language and more basic crossmodal correspondences between color and emotion.

In conclusion, there is likely to be a reciprocal relationship between synesthesia and language. At one level, the representational units of language (graphemes, phonemes, and words) may acquire a perceptual dimension in the minds and brains of synesthetes. At another level, the existence of seemingly universal crossmodal correspondences may guide both the formation of certain types of synesthetic correspondence (e.g., between number and space, pitch and lightness) and also the way that we speak about and conceptualize the world around us.

Synonymy

M L Murphy, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Synonymy is the semantic relation of sameness of meaning either among lexical items or among sentences or propositions, although the latter is also called **paraphrase**. Here we pay particular attention to lexical cases of synonymy. Although synonyms technically have 'the same meaning,' in the everyday use of the term *synonym*, we're usually quite happy to accept as synonyms items with similar, but not identical, meaning. If we did not, thesauri would be short books indeed, because most semantically similar lexical items differ by some dimension or degree of meaning and use. This is because language generally avoids lexical synonymy. Before turning to synonym avoidance, we first consider the properties of synonyms.

Substitution and Synonymy

In logical terms, two propositions are synonymous, or paraphrases of one another, if they have exactly the same truth conditions. In other words, in any situation in which one of the propositions is true, the other must be true, too, and if one is false, then the other is false, too. This means that synonymous propositions are mutually entailing, as is the case for the following sentences (1) and (2):

(1) Tor bought a book from Ulla.
(2) Ulla sold Tor a book.

The proposition expressed by (1) entails the proposition expressed by (2) and *vice versa*, so (1) and (2) are logically synonymous. When defining **logical synonymy** in expressions that are not propositions (such as words), the usual definition is that synonyms are expressions that can substitute for each other in a sentential context without changing the truth conditions of its proposition. Using this diagnostic, we can demonstrate that the verbs *close* and *shut* overlap in meaning (3a and 3b), but are not absolutely substitutable (3c and 3d), and thus not completely synonymous.

(3a) Ingmar {closed/shut} his eyes.
(3b) The door {closed/shut} behind us.
(3c) They closed the meeting with a song.
?They shut the meeting with a song.
(3d) We closed the bar. (= 'We drank until the bar closed' – among other readings)
We shut the bar. (= 'We blocked access to the bar')

The term *full synonymy* is used for words that are logical synonyms in all of their senses. Such synonymy is rare, and is typically found only in words with a rather narrow range of senses, such as some duplicate scientific or species names. For example, the plant

Synonymy

M L Murphy, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Synonymy is the semantic relation of sameness of meaning either among lexical items or among sentences or propositions, although the latter is also called **paraphrase**. Here we pay particular attention to lexical cases of synonymy. Although synonyms technically have 'the same meaning,' in the everyday use of the term *synonym*, we're usually quite happy to accept as synonyms items with similar, but not identical, meaning. If we did not, thesauri would be short books indeed, because most semantically similar lexical items differ by some dimension or degree of meaning and use. This is because language generally avoids lexical synonymy. Before turning to synonym avoidance, we first consider the properties of synonyms.

Substitution and Synonymy

In logical terms, two propositions are synonymous, or paraphrases of one another, if they have exactly the same truth conditions. In other words, in any situation in which one of the propositions is true, the other must be true, too, and if one is false, then the other is false, too. This means that synonymous propositions are mutually entailing, as is the case for the following sentences (1) and (2):

(1) Tor bought a book from Ulla.
(2) Ulla sold Tor a book.

The proposition expressed by (1) entails the proposition expressed by (2) and *vice versa*, so (1) and (2) are logically synonymous. When defining **logical synonymy** in expressions that are not propositions (such as words), the usual definition is that synonyms are expressions that can substitute for each other in a sentential context without changing the truth conditions of its proposition. Using this diagnostic, we can demonstrate that the verbs *close* and *shut* overlap in meaning (3a and 3b), but are not absolutely substitutable (3c and 3d), and thus not completely synonymous.

(3a) Ingmar {closed/shut} his eyes.
(3b) The door {closed/shut} behind us.
(3c) They closed the meeting with a song.
?They shut the meeting with a song.
(3d) We closed the bar. (= 'We drank until the bar closed' – among other readings)
We shut the bar. (= 'We blocked access to the bar')

The term *full synonymy* is used for words that are logical synonyms in all of their senses. Such synonymy is rare, and is typically found only in words with a rather narrow range of senses, such as some duplicate scientific or species names. For example, the plant

name *gorse* refers to exactly the same set of things as *furze* (i.e., a certain yellow-flowered shrub). More common and more polysemous words tend to be synonymous for some of their senses, but not others. For example, in (3) *close* and *shut* share the sense (or senses, if the causative is treated separately) 'to (cause something to) move in order to cover an aperture,' but only *close* has a sense that means 'to bring to an end.' Such logical synonyms can be called **sense synonyms** (but more often than not they are just called *synonyms*).

If we limit our attention to sense synonyms, it is still rare that two words are substitutable for each other in every possible context. Still, many words have similar senses (and denotation) without having exactly the same meaning. For example, *forest* and *woods* (or the British English *wood*) share many aspects of their meaning, but there are things that are forests that one would not call *woods*, and vice versa. Such partial sense similarity is called either *near-synonymy* or *plesionymy* (Cruse, 1986). Near-synonyms may be substitutable in particular contexts, but are not substitutable across a range of contexts.

Many discussions (especially philosophical ones) of synonymy are limited to the above types, in which substitutability is judged only with reference to the truth conditions of the sentences in which the words are substituted – hence the label *logical synonyms* (they are also called *cognitive synonyms*). The notion of substitutability can be extended, however, to consider other, nondenotative aspects of meaning and usage. For example, *child* and *kid* are sense synonyms, but they differ in formality. Thus if *kid* is substituted for *child* in an utterance, then the range of social situations where that utterance is appropriate changes. On this expanded notion of substitutability, logical synonyms may differ in a variety of ways, including those in the following list. (For others, see Palmer, 1981; Hirst, 1995; Murphy, 2003.)

- register: *train – choo-choo*; *salt – sodium chloride*
- implicature: *mislay – lose*; *manage to* [verb] – *succeed in* [verb + *ing*]
- dialect: UK *motorway* – US *highway/freeway*
- affect (speaker's attitude): *freedom fighter – rebel*; *skinny – slender*
- collocation: *ret – steep* (in the sense of 'soak in order to soften': *ret flax* and *steep chilies* but not #*steep flax* or #*ret chilies*)

Taking into consideration all of the various ways in which substitution of a word or phrase might change the communicative import of an utterance, it is difficult to find words that are completely synonymous in all of these dimensions. One possible example is the aforementioned *furze* = *gorse*, which, at least in southern England, are used with exactly the same denotative meaning and no discernable difference in formality, dialect, register, and so forth. Nevertheless, it can still be argued that they are different, in that *gorse* is the more commonly heard name, *furze* is more frequently found in place names, and most individuals use (and possibly know) only one of the terms.

The substitutability diagnostic is also weakened in everyday use of the term *synonym* when the criterion used is 'substitutability' rather than 'mutual substitutability.' For example, *happy* and *elated* are listed as synonyms in many thesauri, but their substitutability is unidirectional, because *elated* is a more specific term than *happy* (we could say that *elated* is a **hyponym** of *happy*), as demonstrated in (4):

(4a) Britt is elated. → Britt is happy. (Thus, we can't say: *Britt is elated, but she's not happy.*)
(4b) Britt is happy. Britt is elated. (So, we can say: *Britt is happy, but she's not elated.*)

This section has demonstrated that there is a considerable gap between the logical definition of synonymy and common ways that linguists and nonlinguists use the term *synonym*. So, while it is perfectly possible that a language has words that overlap in meaning, those word meanings do tend to differ in some aspect, either by having other senses, incompletely overlapping in sense, or differing in some aspect of nondenotative content.

Avoidance of Synonymy

Languages come to have synonyms in a variety of ways. For example, they may be borrowed from other languages or dialects (e.g., *chic-stylish*) or arise via different morphological processes (e.g., *poor-penniless-impoverished*) or different metaphors (*high-stoned*). Yet just as nature abhors a vacuum (*pace* Pascal), language abhors absolute synonymy (Cruse, 1986). For a language to have two words that do exactly the same job is inefficient, but furthermore, it is pragmatically prevented. It is in human nature to assume that choices are made rationally, and so if we choose between one form and another to express a particular meaning, then we assume that there must be reasons why we should prefer one choice over the other. Similarly, we assume that there is a rational explanation when another person chooses one word over another, and so we assume that the word they have chosen is more appropriate to the context than the one that they didn't choose. These pragmatic forces encourage the introduction or maintenance of differences between word meanings, such that when a new word is introduced into one's (or one's language's) vocabulary, we act on the

assumption that it must differ in meaningful ways from any words already in the vocabulary (Bréal, 1900; Clark and Clark, 1979).

Avoidance of synonymy is so strong that in some cases different spellings or pronunciations of the same word are used for different senses of the word. For example, in some varieties of American English, the British pronunciation of *vase* [va:z] has been imported, but it is only for vases that are important or valuable in some way. So, there is a contrast in meaning between [va:z] and [ve:s], shown in (5):

(5a) The museum has acquired a precious Ming [va:z] / [ve:s].
(5b) The [ve:s] (#[va:z]) the flowers came in was horrid, so I threw it away.

So while a language's vocabulary expands, so does its range of lexical meaning differentiations. Thus, avoidance of synonymy is a key motivator of semantic change.

Current Approaches to Synonymy

The role of synonymy in theories of lexical organization varies according to whether the theory posits semantic relations as part of lexical representation or if such relations are derived via relational principles. An example of the former is the WordNet model (*see* **WordNet(s)**) of lexical organization (Fellbaum, 1998), in which the base level of organization in the lexicon is composed of semantically similar 'synsets' (i.e., synonym sets). These groups of synonyms enter as one into other relations, such as hyponymy and contrast. In other approaches, synonymy is usually derived on the basis of similarity of meaning, by which if two words have identical semantic representations (or similar enough representations for a particular context), then they are synonyms. Murphy (2003) takes a contrary position – that synonyms (and other semantic relations) are derived via a pragmatic principle 'relation by contrast.' In this case, synonyms are sets of words that are similar in all contextually relevant ways except their form.

Synonymy is also a central concern in the applied fields of lexicography (e.g., Apresjan, 2000) and computational linguistics (e.g., Edmonds and Hirst, 2002). Both fields are concerned with distinguishing between near-synonyms, either to more precisely define and differentiate semantically similar words, or to allow for automatic selection of the most appropriate word for a context (e.g., in machine translation).

Syntactic Constructions

A Goldberg, Princeton University, Princeton, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

There is currently much theoretical debate concerning the existence and nature of grammatical CONSTRUCTIONS: conventional pairings of form and function. The term *construction* has a long tradition within descriptive grammars, being used to characterize, for example, relative clauses, passives, topicalization, and so on, cross-linguistically. Recently, some theorists have argued that constructions are epiphenomenal, apparent only because of an interacting set of universal, fixed principles with parameters selected on a language-particular basis (Chomsky, 2000); however, the term is still widely used within all linguistic frameworks.

The majority of linguists, recognize the existence of conventional, learned pairings of form and function at least in some cases. For example, each of the following constructions are part of native English speakers' repertoire of their language. Each has unusual quirks in either its formal properties or its semantic interpretation (or both) that make it ill suited for universal status (the stranded preposition construction is unusual not in that it is prescriptively dispreferred, but that it is only found in a few Germanic languages).

As an example of an unusual pattern, consider the Covariational Conditional construction in Table 1 (e.g., *The more you think about it, the less you understand*). The construction is interpreted as involving an independent variable (identified by the first phrase) and a dependent variable (identified by the second phrase). The word *the* normally occurs at the beginning of a phrase headed by a noun. But in this construction it requires a comparative phrase. The two major phrases of the construction resist classification as either noun phrases or clauses. The requirement that two phrases of this type be juxtaposed without conjunction is another nonpredictable aspect of the pattern. Because the pattern is not strictly predictable, a construction is posited that specifies the particular form and semantic function involved (Fillmore *et al.*, 1988).

Over the past two decades, a new theoretical approach to language has emerged that treats constructions as central. Many linguists with varying backgrounds have converged on several key insights that have given rise to a family of approaches, here referred to as *constructionist* approaches (Croft, 2001; Culicover, 1999; Culicover and Jackendoff, to appear; Diessel, 2001; Fillmore *et al.*, 1988; Fillmore *et al.*, in progress; Gleitman, 1994; Goldberg, 1995, 2006; Jackendoff, 2002; Kay and Fillmore, 1999; Lakoff, 1987; Langacker, 1987, 1991; Michaelis and Lambrecht, 1996; Tomasello, 2003). Constructionist approaches embrace the traditional view that patterns such as passive, topicalization and relative clauses are conventional pairings of form and (semantic or discourse) function – *constructions*. At the same time, constructionist approaches share certain foundational ideas with the mainstream 'generative' approach that has held sway for the past several decades (Chomsky, 1965, 1981, 1995, 2000). Both general approaches agree that it is essential to consider language as a cognitive (mental) system; both approaches acknowledge that there must be a way to combine structures to create novel utterances, and both approaches recognize that a nontrivial theory of language learning is needed.

What Counts as a Construction

Some constructionists aim to limit the use of the term CONSTRUCTION to apply to just those grammatical patterns that combine two or more elements; the elements may be either lexical or phrasal, allowing for both lexical and phrasal constructions (Sag *et al.*, to appear). Other theorists apply the term more inclusively to describe any conventional pairing of form and function, including individual morphemes and root words along with idioms, partially lexically filled and fully general linguistic patterns. Examples of each of these types are given in Table 2.

According to the more inclusive use of the term construction, any linguistic pattern is recognized as a construction as long as some aspect of its form or function is not strictly predictable from its component parts or from other constructions recognized to exist. In addition, many constructionist approaches

Table 1 Productive or semiproductive constructions that are unusual cross-linguistically and must be learned on the basis of the input

time *away* construction	*Twistin the night away*
What's X doing Y?	*What's that fly doing in my soup?*
Nominal Extraposition construction	*It's amazing the difference!*
Mad Magazine construction	*Him, a doctor?!*
N P N construction	*house by house; day after day*
Stranded preposition construction	*Who did he give that to?*
Covariational Conditional construction	*The more you think about it, the less you understand*

Table 2 Examples of constructions, varying in size and complexity; form and function are specified if not readily transparent

Morpheme	e.g., *im-, dis-,-ment*	
Word	e.g., *armadillo, remote, or*	
Complex word	e.g., *Daredevil, shoo-in*	
Idiom (filled)	e.g., *Going great guns*	
Idiom (partially filled)	e.g., *Jog* <someone's> *memory*	
Ditransitive (double object) construction	Form: Subj [V Obj1 Obj2] (e.g., *Mike gave her a book; He baked her a carrot cake.*)	Meaning: transfer (intended or actual); see text
Passive	Form: Subj aux VP_{pp} (PP_{by}) (e.g., *The asparagus was chopped by the chef*)	Discourse function: to make undergoer topical and/or actor non-topical

argue that patterns are stored even if they are fully predictable as long as they occur with sufficient frequency (Barlow and Kemmer, 2000; Bybee, 1995; Tomasello, 2003).

Even basic sentence patterns of a language can be understood to involve constructions. That is, the main verb can be understood to combine with an argument structure construction (e.g., transitive, intransitive, ditransitive constructions, etc.) (Goldberg, 1995). The alternative is to assume that the form and general interpretation of basic sentence patterns of a language are determined by semantic or syntactic information specified by the main verb. The sentence patterns given in (1) and (2) indeed appear to be determined by the specifications of *give* and *put* respectively:

(1) Mike gave her a book.

(2) Laura put her coat on the table.

Give is a three argument verb. An act of giving requires three characters: a giver (or agent), a recipient, and something given (or 'theme'). It is therefore expected to appear with three phrases corresponding to these three roles. In (1), for instances, Mike is agent, she is recipient, and a book is theme. *Put*, another three argument verb, requires an agent, a theme (object that undergoes the change of location) and a final location of the theme's motion. It appears with the corresponding three arguments in (2). However, although (1) and (2) represent perhaps the prototypical case, in general the interpretation and form of sentence patterns of a language are not reliably determined by independent specifications of the main verb. For example, it is implausible to claim that *sneeze* has a three argument sense, and yet it can appear in (3). The patterns in (4)–(6) are likewise not naturally attributed to the main verbs:

(3) "He sneezed his tooth right across town." (*Andrew's loose tooth*, Robert Munsch)

(4) "She smiled herself an upgrade." (D. Adams, *Hitchhiker's guide to the galaxy,* Harmony Books)

(5) 'We laughed our conversation to an end.' (J. Hart. 1992, *Sin* NY: Ivy Books)

(6) "They could easily co-pay a family to death." (NYT, 1/14/02)

Examples need not be particularly novel to make the point. Verbs typically appear with a wide array of complement configurations. Consider the verb *slice* and the various constructions in which it can appear (labeled in parentheses):

(7a) He sliced the bread. (transitive)
(7b) Pat sliced the carrots into the salad. (caused motion)
(7c) Pat sliced Chris a piece of pie. (ditransitive)
(7d) Emeril sliced and diced his way to stardom. (*way* construction)
(7e) Pat sliced the box open. (resultative)

In all of these expressions, *slice* means to cut with a sharp instrument. It is the argument structure constructions that provide the direct link between surface form and general aspects of the interpretation such as something acting on something else (7a), something causing something else to move (7b), someone intending to cause someone to receive something (7c), someone moving somewhere (7d), someone causing something to change state (7e) (Goldberg, 1995, 2006). Although most linguists agree that constructions are required for unusual patterns, constructionists invoke constructions for the basic, regular patterns of language as well.

The Functions of Constructions

Different surface forms are typically associated with slightly different semantic or discourse functions. Take for example, the *ditransitive* construction, which involves the form, Subj V Obj1 Obj2 (e.g., (1), (8b), (9b)). The ditransitive form evokes the notion of transfer or 'giving.' This is in contrast to possible paraphrases. For example, although (8a) can be used to mean that Liza bought a book for a third party because Zach was too busy to buy it himself, (8b) can only mean that Liza intended to

give Zach the book. Similarly, although (9a) can be used to entail caused motion to a location (the book is caused to go to storage), the ditransitive pattern requires that the goal argument be an animate being, capable of receiving the transferred item (cf. 9b, 9c). As is clear from considering the paraphrases, the implication of transfer is not an independent fact about the words involved; rather, the implication of transfer comes from the ditransitive construction itself.

(8a) Liza bought a book for Zach.
(8b) Liza bought Zach a book.

(9a) Liza sent a book to storage.
(9b) Liza sent Stan a book.
(9c) ??Liza sent storage a book.

In addition to semantic generalizations, there also exist generalizations about *information structure* properties of the construction, or the way in which a speaker's assumptions about the hearer's state of knowledge and consciousness at the time of speaking is reflected in surface form. In particular, there is a reliable statistically tendency for the recipient argument to have already been mentioned in the discourse (often encoded by a pronoun) as compared to prepositional paraphrases (Arnold *et al.*, 2000; Erteschik-Shir, 1979; Thompson, 1990).

A difference in formal expression typically signals a difference in function. Consider, for example, the Left-dislocation and topicalization constructions in English, which at first may appear to be synonymous:

(10) The giraffe, the mouse saw it. Left-dislocation

(11) The giraffe, the mouse saw. Topicalization

Using the parsed version of the Switchboard Corpus, Gregory and Michaelis (2001) document subtle distinctions between them. The majority of the referents of the fronted NP in TOP are previously mentioned and yet do not persist as topics. The opposite holds for LD's. Thus, the left-dislocation construction is TOPIC ESTABLISHING, whereas the topicalization construction tends to be used for MORIBUND TOPICS.

Languages typically have such special constructions that allow for noncanonical packaging of information. To take another example, Lambrecht (1994) defines SENTENCE FOCUS (SF) CONSTRUCTIONS as constructions that are formally marked as expressing a pragmatically structured proposition in which both the subject and the predicate are in focus. He describes several properties of SF constructions. The function of SF constructions is presentational – namely, to present an entity or an event into the discourse (cf. also Sasse's [1987] entity-central vs. event-central thetic sentences). An English SF construction that introduces an event into the discourse is characterized by having pitch accent only on the logical subject, and not on the predicate phrase, as in (12a, b, c).

(12) Context: What happened?
(a) Her KID is sick.
(b) Her BIKE broke down.
(c) ZACH called you.

The subject in this construction is not topical and cannot be pronominal. For example, (13) can only be interpreted with a narrow focus on the subject argument (an ARGUMENT FOCUS reading) and does not permit a sentence focus interpretation:

(13) HE is sick. (possible context: A: Is she sick?
B: No, HE is sick)

The predicate in the SF construction typically has semantics that are compatible with presentation, with SF constructions crosslinguistically favoring certain unaccusative verbs such as *arrive*, *come*, *die*, and *disappear*. The same function, indicated in English by sentence accent, is marked by different formal means in other languages. The need for a full range of expressive power motivates the existence of marked construction types such as the SF construction.

Facts about the use of entire constructions, including register (e.g., formal or informal), dialect variation, etc. may be stated as part of the construction as well. Constructionist approaches provide a direct way of accounting for these facts, since constructions specify a surface form and a corresponding function.

The Form of Constructions

In order to capture differences in meaning or discourse properties between surface forms, constructionist theories do not derive one construction from another, as is typically done in mainstream generative theory. An actual expression typically involves the combination of at least half a dozen different constructions. For example, the expression in (14) involves the list of constructions given in (15a–15f):

(14) [What did Liza buy the child?]

(15a) *Liza, buy, the, child, what, did* constructions (i.e., words)
(15b) Ditransitive construction (See Table 1 for general description; instantiated by the combination of *what* and *Liza buy the child)*
(15c) Question construction (formed by combining initial *wh- word* with the Subject-Auxiliary construction and clause with a "missing" argument)
(15d) Subject-Auxiliary inversion construction (instantiated by *did Liza*)

(15e) VP construction (instantiated by [*buy the child*])
(15f) NP construction (instantiated by *What*, *Liza*, and *the child*)

Note that 'surface form' need not specify a particular word order, nor even particular grammatical categories, although there are constructions that do specify these features. For example, the ditransitive construction in (11) and discussed above is characterized in terms of a set of argument types. The overt order of arguments in (11) is determined by a combination of a verb phrase construction with the Question construction, the latter of which allows for the 'theme' argument (represented by *What*) to appear sentence initially.

Constructions are combined freely to form actual expressions as long as they are not in conflict. For example, the specification of the ditransitive construction that requires an animate recipient argument conflicts with the meaning of *storage* in (9c) resulting in unacceptability. The observation that language has an infinitely creative potential is accounted for, then, by the free combination of constructions.

Conclusion

The constructionist approach takes a somewhat different view of what is universal about language than mainstream generative approaches. Linguists generally talk of certain constructions as existing in many languages, e.g., the passive construction, relative clause construction, or question construction. However, two constructions in different languages can be identified as instances of the same construction if and only if their form and function is *identical* once other constructions in the language that may differ are factored out. In point of fact, this rarely occurs except in cases of shared diachronic history or language contact (Dixon, 1984; Dryer, 1997; Kim and Maling, 1999; Lambrecht, 1994; Zhang, 1998). As Tomasello (2003) notes, what is truly remarkable is the degree to which human languages differ from one another, given that all languages need to express roughly the same types of messages. Constructional approaches anticipate such fairly wide variability across languages (Croft, 2001; Garry and Rubino, 2001; Van Valin and LaPolla, 1997). Explanations for cross-linguistic generalizations are sought by appealing to general cognitive, pragmatic, and processing factors (e.g., Goldberg, 2003, 2005).

Theoretical Approaches

The syntax of human language is complex, and yet young children developing language typically acquire their system with relative ease and, for some aspects of syntax, in a relatively short time period. Children demonstrate some knowledge of the syntax of their language when they combine words productively, that is, they use combinations that are new, not just imitations, or when they show understanding of different combinations. Understanding the case markers associated with the grammatical roles of subject and object and using these forms in their own utterances is also evidence for syntactic knowledge. Children can understand different structural combinations before they use them in their own speech. This understanding has been demonstrated using experimental techniques such as asking children to act out sentences with toy animals or inanimate objects to represent the grammatical roles (e.g., the active 'The cat chased the dog' versus the passive 'The dog was chased by the cat'), picking out the matching sentence from a set of pictures, or discriminating different sentence patterns using the preferential looking paradigm.

Data and theory are not separable in discussions of syntactic development. Explanations of how children acquire the syntax of their language depend on different theoretical assumptions. According to the Universal Grammar (UG) approach, associated with Chomsky, there are innate principles of human language that limit the structure of human language and guide its acquisition. In addition, parameters restrict variation across languages; the parameters have limited options, usually two. The universal principles become accessible to the child early in the acquisition process; the parameters are set with minimal exposure to the input language. During the course of acquisition, a child may deviate from the syntax of the adult language but only in ways that languages differ from each other; the principles act as constraints. The focus in this approach is the adult language system, the target for acquisition. In contrast, the emergent grammar and usage-based approaches are input-driven, data-driven accounts. The assumption is that children gradually build up the syntactic categories and structures of their language based on the cues available in the input, for example, frequency or regularity of specific constructions. The focus is the process of building up a grammar as the child-learner becomes more familiar with the distribution patterns in the input language.

UG principles should be accessible to children regardless of the language being acquired, and so research with different types of languages is necessary to provide support for the principles. Crosslinguistic research is also necessary for determining the role of specific language characteristics in the acquisition process, for example, how particular properties of a language facilitate or delay acquisition of particular structures. Theoretical Approaches

The syntax of human language is complex, and yet young children developing language typically acquire their system with relative ease and, for some aspects of syntax, in a relatively short time period. Children demonstrate some knowledge of the syntax of their language when they combine words productively, that is, they use combinations that are new, not just imitations, or when they show understanding of different combinations. Understanding the case markers associated with the grammatical roles of subject and object and using these forms in their own utterances is also evidence for syntactic knowledge. Children can understand different structural combinations before they use them in their own speech. This understanding has been demonstrated using experimental techniques such as asking children to act out sentences with toy animals or inanimate objects to represent the grammatical roles (e.g., the active 'The cat chased the dog' versus the passive 'The dog was chased by the cat'), picking out the matching sentence from a set of pictures, or discriminating different sentence patterns using the preferential looking paradigm.

Data and theory are not separable in discussions of syntactic development. Explanations of how children acquire the syntax of their language depend on different theoretical assumptions. According to the Universal Grammar (UG) approach, associated with Chomsky, there are innate principles of human language that limit the structure of human language and guide its acquisition. In addition, parameters restrict variation across languages; the parameters have limited options, usually two. The universal principles become accessible to the child early in the acquisition process; the parameters are set with minimal exposure to the input language. During the course of acquisition, a child may deviate from the syntax of the adult language but only in ways that languages differ from each other; the principles act as constraints. The focus in this approach is the adult language system, the target for acquisition. In contrast, the emergent grammar and usage-based approaches are input-driven, data-driven accounts. The assumption is that children gradually build up the syntactic categories and structures of their language based on the cues available in the input, for example, frequency or regularity of specific constructions. The focus is the process of building up a grammar as the child-learner becomes more familiar with the distribution patterns in the input language.

UG principles should be accessible to children regardless of the language being acquired, and so research with different types of languages is necessary to provide support for the principles. Crosslinguistic research is also necessary for determining the role of specific language characteristics in the acquisition process, for example, how particular properties of a language facilitate or delay acquisition of particular structures. In the following sections, a number of

topics are introduced: early word combinations, the category of verb, verb argument structure, word order and case marking, the prodrop parameter, question formation, passive structures and restrictive relative clauses.

First Word Combinations

When children first join words together, often as early as 18 months, there is evidence that the word sequence is a planned unit; for example, a single intonation contour can be detected, as discussed by Clark (2003). The first combinations represent components of basic events in the child's world and are described in terms of the semantic relations they represent, rather than syntactic. For example, 'throw ball' is an Action–Object sequence. They can also be described in terms of their function; for example, 'more juice' is a request (see examples in Clark, 2003: Table 7.3). Some of the first sequences may be learned as unanalyzed chunks. Others represent a slot and frame pattern, a semi-formulaic pattern such as 'Where's ___.' A number of different items could fit into the slot in this schema.

Following from the first combinations, syntactic development is evident as children demonstrate knowledge of word categories by using words appropriately in different constructions. The development of multiword combinations by one child is illustrated in a study by Lieven *et al.* (2003), who compared the multiword combinations of a two-year-old child produced in one hour with those combinations that she had produced in previous sessions. The child was taped for one hour a day, five days a week, for six weeks, from the age of 24 months. In the last session, 37% of the multiword utterances were novel; most of these differed from the closest match identified in previous sessions by the substitution of one word (or morpheme) in an existing pattern, or schema. Three of these are listed in (1).

(1a) I want___.

(1b) Where's _____.

(1c) That's a _____.

Syntactic Categories and Verb Argument Structure

The syntactic categories of verb and noun are universal in the UG approach, part of the innate knowledge of language. In the construction grammar approach, awareness of the cooccurrence of words in different constructions, that is, the distributional properties, assist children to build up the abstract categories from specific examples. Tomasello (2003), for example, argued that children do not have an innate category of verb. He proposed that children first use a verb only in the construction in which it is heard (the 'verb island hypothesis'). Such verb-specific organization seems to be a feature of the early syntactic combinations of children's utterances.

In discussing the mapping of syntactic categories onto language specific input, Pinker (1994) argued for 'semantic bootstrapping.' He proposed that a set of innate linking rules map innately specified syntactic categories onto innate semantic categories. For example, the agent of an action, if available in a structure, will be linked to the subject role. From this initial mapping, recognition of the distribution properties of the subject would allow the child to link other semantic roles to subject, as in 'I like it' in which the subject has an experiencer role. A major problem with the semantic bootstrapping hypothesis is that the subject role in children's first multiword combinations is frequently a nonagent, and so is not likely to bootstrap children into the system.

Each verb is associated with an argument structure. A verb used transitively requires two syntactic arguments (noun phrases), a subject and an object. Transitive sentences frequently encode a caused action, as in 'He threw the ball,' in which 'he' is the agent causing the ball to move by the act of throwing. Motion verbs have one argument, the subject; however a goal argument may be added to indicate the end point of the motion, as in (2a), or a locative argument to show where the activity took place, as in (2b). In contrast, the verb 'put' requires three arguments, subject, object, and locative, as in (2c). In order to use a verb appropriately, a child must know the argument structure of the verb, as well as whether it has more than one argument structures, for instance, as does 'grow,' which is transitive in 'She grew some flowers' and intransitive in 'The flowers grew.' A number of proposals have been made as to how this knowledge is acquired.

(2a) He ran to the park.

(2b) She walked in the park.

(2c) The child put the car on the table.

The verbs that are used first tend to be those that are frequent in the input, which, in English, include 'do,' 'make,' and 'go.' These are referred to as general-all-purpose verbs, 'light' verbs or path-breaking verbs (Ninio, 1999). One view of how children learn the argument structure of verbs is that they attribute a meaning to a verb from the nonlinguistic context

and associate that verb with the particular sentence structure (frame) in which it is heard. A new verb that seems to overlap in meaning will then be used in a similar frame. Thus verbs are linked on the basis of semantic similarity, and this connection determines how they are used. The 'syntactic bootstrapping' hypothesis (Gleitman, 1990) presents another view. Because there is a close link between the meaning of a verb and the syntax, it is suggested that the syntax acts like a 'mental zoom' to help children interpret a new verb. That is, the sentence frame in which a new verb appears contributes to the child's meaning of the verb. Knowing, for example, that a verb with two noun arguments typically encodes a causal element, as in 'He dropped the book,' helps a child assign a causal meaning to the verb.

The plausibility of syntactic bootstrapping is evident from a study on the use of 25 verbs in different syntactic frames in the speech of 57 mothers to their children aged one to two years. Naigles and Hoff-Ginsberg (1995) showed that the verbs in different semantic categories appeared in different syntactic frames, and that individual verbs could be distinguished by the set of frames in which they appeared. That is, the input provides a child with a model for the semantic-syntax link. There is also support from experimental data. Using a preferential looking task, Naigles (1996) showed that toddlers make use of syntactic bootstrapping by the age of 24 months. That is, they interpreted a novel verb differently depending on the number of noun phrases accompanying it. A causal interpretation was given to a verb with two arguments and a spontaneous interpretation to the same verb with one argument. In another study by Naigles, when children were presented with a familiar verb in an odd sentence frame for that verb, for example 'The zebra goes the lion' or 'The zebra brings to Noah,' two-year-olds modified the meaning of the verb to fit the sentence frame, interpreting the first sentence as the causative 'The zebra makes the lion go,' and the second as 'The zebra brings something to Noah.' That is, the two-year-olds were frame compliant; in contrast, adults are verb compliant, relying on the known meaning of the verb to interpret such odd sentences.

Children do occasionally overgeneralize verbs, using them in nonadult-like structures, as shown in 'I'll disappear it' for 'I'll make it disappear.' Here the intransitive verb 'disappear' is used causatively in a transitive structure. Such overgeneralizations have been reported in a number of languages including English (Bowerman, 1982), Portuguese (Figueira, 1984), and Thai (Yumitani, 1998), with more intransitive verbs used in transitive structures than the reverse.

Word Order and Case Marking

Languages rely on word order or morphological cues (subject-verb agreement or case marking), or a combination of factors to encode the syntactic arguments. These cues provide the focus for children's developing knowledge of argument structure relevant to their language. In English, there are strict ordering restrictions for the subject (S) and object (O) in relation to the verb (V). The subject comes before the verb; the object follows. Data from studies using preferential looking tasks have shown that children are able to distinguish different word orders by the age of 24 months.

Not all languages have such a rigid word order. In Turkish, the subject can be positioned before or after the verb, as can the object; thus six orders are possible: SVO, SOV, OSV, OVS, VSO and VOS. An accusative case marking on definite objects in Turkish allows the object to be identified whatever its position. However, this flexibility means that the child needs to learn the case form and its function. Within a language, there may be specific variations on word order; for example, pronominal objects are placed before the verb in French while lexical objects follow. Bates and MacWhinney (1989) reported data from 13 languages, comparing the cues used by children and adults to identify the subject and object in transitive sentences in their language. Slobin (1982) compared the ages at which children acquiring English, Turkish, Serbo-Croatian, or Italian could interpret transitive sentences appropriately. The Turkish children were successful at the youngest age, 24–28 months, whereas the Italian and English were comparable in performance only at 32–36 months and the Serbo-Croatian at four years of age. Slobin credited the transparent case system of Turkish as facilitating understanding of the transitive structure. Processing local cues (case marking) to identify syntactic arguments appears to be easier than processing word order for a young child. However, when the case markers are variable in form, as in Serbo-Croatian, the task of identifying the case markers will be more complex.

Children's preferences for word order may not always match the model provided in the input, as shown in a study on double object constructions with Korean children. By the age of four, Korean children interpret OSV word order by relying on the nominative case marker to identify the subject and the accusative case marker to identify the object. Before that age, the first noun is typically taken to be the subject and the second noun the object. In a study by Cho *et al.* (2002) to test Korean children's understanding of word order and case marking, the test sentences contained two objects, a direct object

with accusative case and an indirect object with dative case. The sentences included either two animate objects, as shown in (3a), or two inanimate objects, as shown in (3b). (The dative case form is *hanthey* for animate nouns and *ey* for inanimate nouns).

(3a) So-hanthey kom-ul
Cow-DAT bear-ACC
mile-ceu-llay-yo?
push-BEN-FUT-SENTENDER
'Will you push the bear to the cow?'

(3b) Moca-ey sonswuken-ul
cap-DAT handkerchief-ACC
tencye-cwu-llay-yo?
throw-BEN-FUT-SENTENDER
'Will you throw the handkerchief at the cap?'

The children, aged from four to seven, performed better on the sentences in which the dative object followed the accusative object (AD) than when it preceded it (DA), which is the order in which the event happens, with the dative object as the endpoint of the action. Cho *et al.*, referred to this result as the iconicity hypothesis. Of interest is that in the speech of mothers to children for three dyads over a six-month period when the children were aged three years, the dative-first order (DA) was the most frequent when both objects were included in the sentence. (In Korean, an object is often omitted; see next section). The children's preferred order did not match the order modeled most frequently in the input, indicating that children move beyond the input, and may follow different strategies from adults.

The Prodrop Parameter and Argument Ellipsis

Within the UG approach, determining what counts as evidence for the setting of a specific parameter is often debated because performance factors interact with syntactic knowledge and so it is not always clear whether the parameter is set. For example, in Italian, as in a number of other languages, a pronoun subject ('I,' 'you,' 'we') can be omitted. This language variation is captured by the prodrop parameter: languages are either + prodrop or − prodrop.

Because children do not know which language they will acquire, it is assumed that they start with the same default setting and with limited experience set the parameter appropriately for their language. Children acquiring both types of language omit subjects in their early verbal utterances, leading to the conclusion that the parameter is yet to be set by children acquiring English, a nonprodrop language. Valian (1991), however, examined the number of subjects dropped by children acquiring Italian and children acquiring English and found that Italian children omitted twice as many subjects as children acquiring English. This difference in the number of nonovert pronominal subjects across the two languages was argued to support the view that the parameter had been already set. Valian explained the nonovert subjects in the speech of the children acquiring English as a performance limitation. That is, children's limited memory and processing skills affect how many syntactic arguments they produce.

A usage-based explanation for nonovert subjects is that children become sensitive to patterns of increasing length in the input language and build up knowledge about whether subjects are required or not, based on their experience. In addition to pronominal subject ellipsis, many languages also allow lexical arguments to be omitted, and not just subjects. Korean, Chinese, Japanese, Sesotho (Sotho, Southern), Warlpiri, and Inuktitut are just some of the languages that allow lexical arguments to be nonovert. In these languages, a sentence might consist of just a verb, or a verb with modifiers. Yet, a transitive verb such as the verb for 'eat' will be interpreted as 'Someone ate something.' The identity of any missing argument is inferred from the linguistic or nonlinguistic context. Ellipsis of lexical arguments is usually given a discourse explanation, for example, de Bois (1987) proposed that ellipsis is linked to Preferred Argument Structure; old (assumed) information in discourse is often assigned to the subject slot of transitive verbs, whereas new information is assigned to the intransitive subject or the transitive object. When adults omit arguments, it is generally old information that is omitted. In their early utterances, children also seem to omit information that can be assumed from context. Children acquiring a language that allows arguments to be nonovert gradually learn the constraints that are relative to that language as their knowledge of discourse linking strategies develops. In a case marking language, the case markers will not be available if the arguments are nonovert. This unavailability will have an impact on how readily children master the case forms and their function and thus may delay their syntactic knowledge.

Questions

Questions in English involve inversion: the auxiliary appears before the subject noun phrases as in the 'yes-no' question 'Are you hungry?' Information questions also include a wh-word such as 'where,' 'who,' 'what,' 'when,' and 'why.' The wh-word appears before the inverted auxiliary as in 'Where did she go?' Proponents of UG argue that question formation is too difficult to learn on the basis of

Figure 1 Structure showing I in relation to C.

patterns in the input and that errors would be predicted to be frequent. Question formation relies on a UG principle of movement, a structure dependent principle since the element to be inverted is not determined by linear order but by its structural position. For example, in the question 'Who did Mary want to invite?' the questioned element represented by 'who' is the logical object of the verb 'invite' and must be moved from the object position following the verb. The element to be moved varies, so that from the structure 'The boy who is reading a book is hungry,' the second 'is' is moved to form the question 'Is the boy who is reading a book hungry?' The moved element is the auxiliary in the main clause.

In this account, the elements in the I position are moved to the C position (see Figure 1). IP stands for Inflection phrase and CP for complementizer phrase. An auxiliary verb or a modal is moved from the I position to the C position, as in 'Can she stay?'; if there is no auxiliary or modal to move, as in 'They eat,' the auxiliary 'do' is used as a default to be inserted into I so that it can move to C, as in 'Do they eat?' The features of tense and person are generated in the I node, as are modals. The verbs 'have' and 'be,' both of which act as lexical verbs, are generated in the VP, and move to I in order to be moved to C in question formation, as in the question 'Is Teddy in the box?' Tense, number, and person are marked on the inverted element, not the lexical verb.

Young children acquiring English first produce wh-questions such as 'What you doing?' and 'Where this goes?' These do not have overt auxiliaries. Later, questions appear with inversion, such as 'What are you doing?' but these may appear alongside non-inverted auxiliaries such as 'What you can do?' [You can hear examples of a type of error in which a wh-word remains in its original position and is copied in sentence initial position; listen to the examples on two short video clips available from the LSA archives at the University of Georgia website. The videos 'What you think what she said' and 'Who do you think who's in the box?' were submitted by Stephen Crain, Rosalind Thornton, and Graciela Tesan. They show footage of two-year-olds asking questions.] Many proponents of UG support a continuity approach; they argue that the universal principles are available to children from the early stages; for question formation, it would be the principle of movement that controls inversion. To explain the deviations from the adult grammar, it is argued that while the principal is available to the children, they do not have all the language-specific properties, for example, knowledge of the features of tense, number, and person (Santelmann *et al.*, 2002).

Usage-based explanations offer another explanation as to why some questions appear with inverted auxiliaries while others do not: the frequency of specific constructions in the input influences which combinations show inversion. If a child hears a combination of a specific wh-word with a specific auxiliary, she will learn the combination as a unit. In the data reported by Rowland and Pine (2000) from transcriptions of Adam when he was aged 2; 3–4; 10, only three specific combinations of wh-word and auxiliary were used first, both with and without inversion: 'How can,' 'What's,' and 'Why is.' Other combinations of wh-word and auxiliary appeared only in one form, either the inverted or noninverted form. In 55 one-hour transcripts of Adam over the period studied, combinations of wh-word + auxiliary not previously inverted by Adam started to show inversion based on the frequency with which a model was provided in the input. Once children master question formation in simple sentences, it would be assumed the knowledge would generalize to complex sentences. (Adam is one of the three children in Roger Brown's classic study. The Adam files can be accessed on the CHILDES database [MacWhinney and Snow, 1985]).

Experimental findings also show that frequency in the input can help children form a more abstract representation of the role of auxiliary, necessary knowledge for question formation. Valian and Casey (2003) trained children aged 30–38 months over a period of four weeks by modeling or repeating a question; these children were better able to imitate questions after the training than were children who received no such training. The children were also better able to use auxiliaries that had not even been used in the training, indicating that the abstract representation for the role of auxiliaries develops as children attend to the structures in the input.

Passives

Passive structures are not frequent in the speech of children under the age of three who are acquiring

English; nor are they very frequent in the input. In interpreting passives, children who are acquiring English typically go though a stage of choosing the first noun as the agent. Thus for the sentence 'The cat was chased by the dog,' the first NP, 'the cat' will be chosen, incorrectly, as the agent. To account for the apparent late acquisition of passives, Borer and Wexler (1987), following the UG approach, proposed that the principles underlying movement are late in maturing. They argued that A-chains (argument chains) are not formed early in the acquisition process and thus verbal passives are not produced by young children, although adjectival passive such as 'The box is broken' are. A-chains are formed to link a moved element to its logical position; thus when an object is moved to subject position to form a passive an A-chain is formed. However, verbal passives are frequent in the speech of young Sesotho children (Demuth, 1989). They are also frequent in the input to Sesotho children, and this frequency seems to be the influencing factor in their early acquisition. Similarly, passives are frequent in the input to children acquiring Inuktitut (Allen, 1996; Allen and Crago, 1996) and in the input to children acquiring Quiche Mayan (Pye and Quixtan, 1988) and in both of these languages, children use passives more than children acquiring English. Thus, data on the acquisition of passives does not provide support for the maturation hypothesis.

Relative Clauses

A restrictive relative clause functions as a modifier of one of the arguments in the main clause. For example, in (4a), the relative clause 'that bit the cat' modifies the main clause object 'the horse.' In (4b), the relative clause modifies the main clause subject 'the dog.' In (4c), the relative clause also modifies the main clause subject but that noun functions as the object of the relative clause verb 'chased' and so can be referred to as an object-extracted relative clause.

(4a) The dog chased the horse that bit the cat.

(4b) The dog that chased the cat is a poodle.

(4c) The dog that the cat chased is a terrier.

Many of the early experiments testing children's knowledge of relative clauses adopted an act-out task using full relative clause structures as in (4). Some relative structures were found to be more difficult to interpret than others. Although there was some inconsistency across studies, relative clauses modifying the main clause subject were generally harder to interpret than object relative clauses, possibly because the embedded clause interrupts the flow of information. In addition, children were typically found to interpret an object relative clause as if it were conjoined to the main clause (Tavakolian, 1981). That is, sentence (4a) would be interpreted as 'The dog chased the horse and the dog bit the cat' rather than 'The horse bit the cat and it was this horse that the dog chased.'

Hamburger and Crain (1982) modified the standard act-out procedure to create felicitous conditions. They argued that findings from studies using the standard act-out task underestimated the knowledge children have about relative clauses. Since a restrictive relative clause identifies a specific referent, they provided two examples of each animal. The children could then pick the one that met the description provided in the relative clause, e.g., two horses would be provided for sentence (4a). They tested only relative clauses of the type shown in (4a). The results showed that although the accuracy of the five-year-olds was better than for the three- and four-year-olds tested, even the younger children were better able to understand the structures than in previous studies using the standard act-out task.

Children acquiring English start to produce relative clause structures spontaneously at age two. Clark (2003) gives a number of examples from her son at that age. They include 'I leave it over there where I eat supper' and 'I'm going to show you where Mr Lion is.' These early structures are not always full relative structures, but function in the same way, introducing modifying information to a preceding or assumed noun. As Clark points out, common features of these early relative clauses is that they are placed at the end of the sentence and lack a relative marker such as 'that' or 'who.'

In a study on spontaneous relative clauses produced by four English-speaking children aged from 1;9–5;2, Diesel and Tomasello (2000) identified 75% of the examples produced by the children at age two as presentational relative clauses. A presentational structure is used to introduce new information. Examples included: 'Here's a mouse go sleep' and 'That's a turtle swim.' Both examples show reduced relative structures. Most lacked a relative marker and did not contain a clause embedded in another, the characterization of a relative structure. Instead, they were one-clause structures. In addition, most examples included intransitive verbs, so limiting the number of arguments expressed. In the input to the children, 54% of the relative structures were presentational. Thus, the children had frequent models from which to extract semiformulaic patterns into which different items could slot.

Conclusion

The acquisition of the syntax of a language is not instantaneous. However, there is clear evidence that by the age of three, children know a lot about the syntax of their language. Knowledge of complex sentence structures, not covered in this review, continues to develop after this age. Different perspectives are taken on how syntactic knowledge develops. Proponents of UG propose that universal principles guide the child in the acquisition task; they argue that children extend beyond their experience with a particular language. Proponents of data driven and emergent grammar approaches argue that children learn from the data provided by the language; language specific properties guide the acquisition process. How children's spontaneous productions and how their performance on experimental tasks is interpreted are very much dependent on the theoretical assumptions made.

Syntactic Features and Feature Structures

J P Blevins, University of Cambridge, Cambridge, UK

Classical grammars approach grammatical analysis essentially as a problem of classification, as Matthews (1991: Sect. 10) observes. An utterance is divided into parts, which are assigned to word classes and then subclassified in terms of their 'accidents' or properties. A fundamentally similar conception of grammatical analysis is incorporated in modern feature-based grammars. Modern approaches have developed more complex and somewhat more imposing constraint languages and formal representations. But underlying this feature technology is a core of relatively straightforward claims and hypotheses. Foremost among these is the idea that grammatical properties and dependencies – local and nonlocal – can be described in terms of complex-valued features. It is the use of complex feature values to express grammatical dependencies that principally distinguishes approaches such as GPSG, LFG, and HPSG from models that attribute the 'flow' of feature information to constituent-structure displacements or other mechanisms.

A second key idea is that feature matching within an endocentric phrase need not be confined to the word-class features that define major categories such as noun, verb, and adjective. All feature-based approaches provide strategies, of one sort or another, which allow a phrase to share the inflectional properties of its syntactic head. These strategies allow the number features of a noun to be shared with the noun phrase that it heads, and permit the tense and agreement features of a verb to be shared with the verb phrase or clause that it heads. The resulting syntactic analyses are, so to speak, 'bushy,' as the feature information at a given node tends to be relatively dense, but there are comparatively few nodes between the 'root' and 'leaves' of an analysis.

Feature-based approaches also tend to regulate grammatical dependencies *constructively*, by consolidating the properties of heads and arguments, agreement targets, and controllers, and even 'fillers' and 'gaps.' In most approaches, the elements in a grammatical dependency are identified as the same structure. The early feature-based accounts, described by Shieber, 1986, identify feature structures by applying a symmetrically destructive *unification* operation. In more recent accounts, the elements in a grammatical dependency are interpreted as 'co-descriptions' of a common structure. This reflects a general shift to a description-based perspective, in which grammatical expressions, such as rules, constraints, or entries, are interpreted as *descriptions*, and objects such as trees and/or feature structures are interpreted as structures that *satisfy* those descriptions. This separation has led to the development of feature logics for grammatical description (Johnson, 1988; King, 1989; Carpenter, 1992), providing a point of contact between feature-based approaches and other deductive grammar formalisms, such as the Lambek calculus.

The Structure and Distribution of Feature Information

To a great extent, the form of a syntactic analysis reflects assumptions about the organization and distribution of morphosyntactic information. In simple terms, feature-based models adopt comparatively simple constituent structures and more articulated feature structures, whereas transformational accounts assume relatively simple feature bundles, but highly complex constituent structures. This contrast can be traced to different ideas about the distribution of features.

The prerequisites of a feature-based approach are fully present in standard theory transformational grammars, which contain atomic features, complex symbols, and a lexical insertion rule whose nondistinctness condition (Chomsky, 1965: 121) anticipates operations like unification. Nevertheless, the descriptive potential of these devices is severely constrained in the standard theory by the fact that complex values

Classical grammars approach grammatical analysis essentially as a problem of classification, as Matthews (1991: Sect. 10) observes. An utterance is divided into parts, which are assigned to word classes and then subclassified in terms of their 'accidents' or properties. A fundamentally similar conception of grammatical analysis is incorporated in modern feature-based grammars. Modern approaches have developed more complex and somewhat more imposing constraint languages and formal representations. But underlying this feature technology is a core of relatively straightforward claims and hypotheses. Foremost among these is the idea that grammatical properties and dependencies – local and nonlocal – can be described in terms of complex-valued features. It is the use of complex feature values to express grammatical dependencies that principally distinguishes approaches such as GPSG, LFG, and HPSG from models that attribute the 'flow' of feature information to constituent-structure displacements or other mechanisms.

A second key idea is that feature matching within an endocentric phrase need not be confined to the word-class features that define major categories such as noun, verb, and adjective. All feature-based approaches provide strategies, of one sort or another, which allow a phrase to share the inflectional properties of its syntactic head. These strategies allow the number features of a noun to be shared with the noun phrase that it heads, and permit the tense and agreement features of a verb to be shared with the verb phrase or clause that it heads. The resulting syntactic analyses are, so to speak, 'bushy,' as the feature information at a given node tends to be relatively dense, but there are comparatively few nodes between the 'root' and 'leaves' of an analysis.

Feature-based approaches also tend to regulate grammatical dependencies *constructively*, by consolidating the properties of heads and arguments, agreement targets, and controllers, and even 'fillers' and 'gaps.' In most approaches, the elements in a grammatical dependency are identified as the same structure. The early feature-based accounts, described by Shieber, 1986, identify feature structures by applying a symmetrically destructive *unification* operation. In more recent accounts, the elements in a grammatical dependency are interpreted as 'co-descriptions' of a common structure. This reflects a general shift to a description-based perspective, in which grammatical expressions, such as rules, constraints, or entries, are interpreted as *descriptions*, and objects such as trees and/or feature structures are interpreted as structures that *satisfy* those descriptions. This separation has led to the development of feature logics for grammatical description (Johnson, 1988; King, 1989; Carpenter, 1992), providing a point of contact between feature-based approaches and other deductive grammar formalisms, such as the Lambek calculus.

The Structure and Distribution of Feature Information

To a great extent, the form of a syntactic analysis reflects assumptions about the organization and distribution of morphosyntactic information. In simple terms, feature-based models adopt comparatively simple constituent structures and more articulated feature structures, whereas transformational accounts assume relatively simple feature bundles, but highly complex constituent structures. This contrast can be traced to different ideas about the distribution of features.

The prerequisites of a feature-based approach are fully present in standard theory transformational grammars, which contain atomic features, complex symbols, and a lexical insertion rule whose nondistinctness condition (Chomsky, 1965: 121) anticipates operations like unification. Nevertheless, the descriptive potential of these devices is severely constrained in the standard theory by the fact that complex values

are confined to the preterminal level on which they are introduced. Similar constraints on the distribution of morphosyntactic properties likewise determine the form of analyses in late transformational models, such as Chomsky, 1995.

Syntactic analyses in these accounts are much more 'spindly' than those in feature-based models, as the information at any given node tends to be sparse, but there are many more nodes over which information is distributed. This organization reflects the view that word class features are fundamentally different in character from other types of lexical or inflectional properties. This view in turn can be traced to the fact that the 'morpheme class marks' in Harris (1951: 263) only represent word class and contrasts between simple and complex expressions. This focus on word class and phrase type was retained when Chomsky (1970) recast Harris' distributional model as X-Bar Theory. The X-bar conventions thus provide a general mechanism for matching the word-class features of an endocentric phrase and its syntactic head. These conventions do not, however, regulate the compatibility of other types of features. Within the transformational paradigm, this has led to the wholesale reclassification of inflectional properties as word-class features, associated with various types of abstract formatives. Reclassifying traditional properties such as tense or aspect as features of functional heads allows these properties to be regulated by the restricted X-bar conventions. Agreement properties are similarly balkanized into a sequence of abstract formatives, each with a category that corresponds to a traditional agreement feature.

The Role of Complex-Valued Features

Feature-based models take a more conservative view, in which the properties traditionally associated with a word class are directly assigned to the lexical items in that class. Verbal properties, such as tense, aspect, mood, and voice, are directly associated with verbs, and nominal properties such as person, number, gender, and case are associated with nouns. However, the key innovation in feature-based approaches involves the use of complex feature values to regulate grammatical dependencies. The analysis of subject-verb agreement provides a useful illustration. The subject agreement demands of an English verb such as *skis* may be expressed by assigning *skis* a complex-valued SUBJ(ECT) attribute that contains the features that represent third person and singular number. In a simple feature system, these might be [PER 3] and [NUM *sg*]. Agreement between *skis* and *he* in (1) is then keyed to a requirement that the subject features associated with the verb must be compatible with the grammatical features of its syntactic subject. The details of this analysis vary across approaches, though the leading idea is that the properties of the agreement 'controller' *he* and the agreement 'target' *skis* must contain no features that conflict. In the early feature-based models described in Shieber (1986), this is regulated by first assigning the subject *he* and the verb *skis* the partial feature structures in (1). The compatibility of these structures is then determined by unifying them, which defines the structure associated with *he skis* in (1)

(1) Agreement via complex-valued agreement features

In models such as LFG (Kaplan and Bresnan, 1982) or HPSG (Pollard and Sag, 1994), the agreement constraints in the entries for *he* in (2a) and *skis* (2b) are interpreted as partial descriptions of an agreement matrix. Compatibility between the agreement properties of *skis* and those of its syntactic subject is determined by interpreting the constraints in (2a) and (2b) as descriptions of the same feature structure, in accordance with the constraint stated informally in (2c).

(2a) *he*: {(per = 3), (num = *sg*), (gend = *masc*)}
(2b) *skis*: {(subj per = 3), (subj num = *sg*) . . . }
(2c) A verb's subj features describe the same structure as the features of its syntactic subject.

On either a unification- or description-based alternative, agreement is a symmetrical relation, unlike the asymmetrical 'copying' relations assumed in many transformational accounts. There is no requirement that agreement properties must be uniquely associated with the agreement target or controller, or that either element must in any sense be more informative than the other. Symmetry is widely viewed as a virtue, as order-independent formalisms fit particularly well with incremental models of comprehension or production. Nevertheless, it remains to be seen whether a symmetrical approach can provide illuminating analyses of all of the cases that motivate the traditional distinction between agreement 'controllers' and 'targets' (Corbett, 1991).

The introduction of complex-valued features overcomes many of the descriptive limitations of simple phrase structure systems, as originally noted in Harman (1963). For example, the subcategorization demands of a transitive verb can be represented straightforwardly by a complex-valued OBJ(ECT) attribute. The verb's demands will be satisfied if its OBJ properties are compatible with the properties of its syntactic object, where compatibility can again be determined in unification- or description-based

terms. Nonlocal dependencies can likewise be described by means of a chain of local dependencies involving complex-valued attributes.

In the subject raising example in (3a), the expletive *it* occurs as the subject of *seems* but ultimately satisfies the valence demands of the embedded weather verb *raining*. The term 'raising' reflects the fact that transformational descriptions of this pattern tend to introduce *it* as a syntactic subject of *raining*, which is then advanced to the matrix subject position by means of constituent-structure displacements. Complex-valued features permit an account of this pattern in terms of a sequence of identities. The idea is just that the SUBJ features of a subject-raising verb are interpreted as describing the same feature structure as the SUBJ features of its complement, in accordance with (3c). If, as often assumed, *seems, have*, and *been* are all classified as subject-raising verbs, then the SUBJ features of *seems* will describe the same structure as the SUBJ features of *have*. The SUBJ features of *have* will describe the same structure as the SUBJ values of *been*, and the SUBJ features of *been* will in turn describe the same structure as the SUBJ features of *raining*. Through this chain of identities, the SUBJ demands of each of the verbs in (3a) will come to describe the same structure. In order to satisfy the demands of *raining*, this structure must be the structure associated with the expletive subject *it*. Hence *seems* must select *it* in (3a).

(3a) It seems to have been raining.
(3b) The subject-raising (SR) verbs in English include *seem*, *have*, and *be*.
(3c) A SR verb's SUBJ features describe the same structure as its complement's SUBJ features.

Complex-valued features also permit the description of grammatical dependencies that span potentially unbounded domains, as initially demonstrated by the treatment of extraction constructions in GPSG (Gazdar *et al.*, 1985). The principle is the same as in the treatment of raising constructions, though different grammatical attributes may mediate between a 'filler' and 'gap.'

Compatibility and Identity

Individual feature-based approaches differ in a variety of technical respects, such as the relative informativeness of the structures that are taken to satisfy a grammatical description. Whereas structures in LFG are 'minimal' solutions to a set of constraints, a structure in HPSG is assumed to be specified for any properties that are appropriate for structures of its type. The organization of structures into hierarchies of 'types' is another distinctive characteristic of HPSG accounts.

A number of more general issues also arise within the broad class of feature-based formalisms. One basic issue concerns the use of unification or identity to model grammatical 'compatibility.' It has often been observed that a single element appears to be able to satisfy multiple, conflicting demands if it is neutral for the conflicting features. In German, for example, a verb form such as *kaufen* allows either the 1pl subject *wir* or a 3pl subject such as *sie*. This correlates with the fact that *kaufen* is compatible with both *wir* and *sie* in the coordinate structure in (4).

(4) ...*weil wir das Haus und sie den Garten kaufen*.
...because we.1pl the house and they.3pl the garden bought
'...because we bought the house and they the garden.'

As Ingria (1990) notes, 'destructive' operations like unification would be expected to eliminate the feature neutrality that allows *kaufen* to combine with *wir* and *sie* in (4), since unifying the agreement features of *kaufen* with the features of either subject will yield an agreement matrix with person features that conflict with those of the other subject. A similar issue arises on a description-based alternative that interprets the SUBJ features of *kaufen* as describing the same structure as the features of *wir* and *sie*, since no consistent structure can satisfy the properties of *kaufen*, *wir*, and *sie*. Ingria proposes that compatibility is more appropriately regulated by a 'nondistinctness' check. However, a simple check would sacrifice feature-based accounts of nonlocal dependencies. It is the identification of SUBJ values in (3a) that associates *seems* with the subject demands of *raining*. If the SUBJ features of a raising verb need only be nondistinct from those of its complement, nothing would ensure a higher verb 'inherits' SUBJ features of a lower verb.

There is a variety of options between distinctness and identity, and there is as yet no clear consensus regarding the best general solution to the challenge that Ingria articulates. One possibility is that the properties of a head and dependent are, in effect, 'consolidated upward' and associated with the constituent formed by combining the head and dependent. On this alternative, the third structure in (1) would be associated with the sentence *he skis*. The subject-verb agreement constraint would require that SUBJ properties of *skis* in (2b) and the properties of *he* in (2a) must both describe this structure. If, as in (4), a verb is affiliated with multiple clauses, its SUBJ properties would be required to describe the structure

associated with each clause. The properties of a subject would also be required to describe the structure associated with the clause that contains it. But nothing would enforce the compatibility of subjects in different clauses. The SUBJ features of each verb in (3a) would likewise be required to describe the structures associated with the verb phrases under which it is embedded. However, nothing would require an embedded structure to satisfy the properties of a higher verb. Thus, the SUBJ structure associated with the matrix verb phrase in (3a) would satisfy the SUBJ features of *raining*, but the SUBJ structure associated with the verb phrase headed by *raining* would not satisfy the agreement demands of *seems*.

In short, a transitive relation is required to 'propagate' compatibility demands over a nonlocal domain, and identity is a canonically transitive relation. However, relations weaker than identity (or operations less symmetrically 'destructive' than unification) might ultimately be more appropriate for regulating grammatical dependencies within a feature-based approach. One might then ask whether token-identity is ever really needed. The constraints in (2c) and (3c) both interpret two descriptions as referring to the same structure, and identity statements are generally interpreted as requiring token identity of structures. Yet it is by no means clear that the same compatibility demands will not be enforced if identity constraints are satisfied by type-identical structures. In effect, this amounts to moving identity out of feature structures and confining it to the constraint language of a feature-based approach. The treatment of other logical operators provides a model. Karttunen (1984: 30) introduces negative constraints on pair nodes that 'prevent the nodes from ever becoming alike.' In description-based models, a negative (or disjunctive) constraint is interpreted as describing a family of satisfying structures. There are no negative or disjunctive structures, just negative or disjunctive descriptions of structures. This type of reinterpretation can also be applied to identity, so that there are no reentrant (token-identical) structures, only identity constraints, which are satisfied by type-identical structures.

In summary, the classification of features and the relative complexity of feature structures and constituent structures are issues that clearly distinguish feature-based approaches from transformational alternatives. Within the class of feature-based models, one can identify strategies for describing grammatical dependencies, model-theoretic perspectives on grammatical analysis, and a number of formal and empirical questions that these strategies and perspectives raise.

Syntactic Variables and Variable-free Syntax

M Steedman, University of Edinburgh, Edinburgh, UK

Introduction

Chomsky's influential analysis of human language in terms of Transformational Grammar argued two points. The first was that the lowest levels of what later became known as the Chomsky Hierarchy of formal language classes characterizable by both rule types and automata, namely the Finite State Languages and the Context-Free Languages, could not adequately capture the phenomenon. The second was that rules of a different kind, called Transformations, were appropriate for the purpose.

Transformations were defined as tree-modifying rules, and were not initially identified with any specific level in the Chomsky hierarchy, although they were soon shown to lie at the highest level. Some of them included variables over sequences of words and constituents. Such rules showed a tendency to 'overgenerate' – that is, to allow strings that were not allowed in the language under analysis (or indeed in **any** language) – and to require the specification of attendant constraints and conditions to confine the grammar to generating all and only the legal sentences.

Work in theoretical linguistics then began to proceed along two paths. On the first path, the emphasis was on descriptive adequacy, in the sense of generatively accounting for all and only the sentences of any given language, and on analyzing the constraints themselves, in the reasonable expectation that this process would reveal important generalizations. This approach tended to be accompanied by a corresponding reduction in the variety of the transformational rules themselves to a small number of operations of great generality involving variables. This approach, which was led by Chomsky himself, was the direct descendant of Transformational Grammar, and was essentially 'top-down' or phenomenological in orientation, emphasizing the Autonomy of Syntax – that is, its independence as an object of study from other modules such as semantics or the processor, a position that Chomsky defended in a series of philosophical works starting with *Cartesian Linguistics* (1966).

On the other path, the emphasis was on identifying grammar formalisms of lesser expressive power, without the use of variables, from which the behaviors described by constraints on transformations would emerge without requiring explicit stipulation.

It is this sense of the term 'variable-free syntax' that is the present concern. (The term is sometimes used in a quite different sense within some categorial approaches stemming from Montague Grammar to refer to a much stricter regimen pioneered by Szabolcsi and Jacobson, forbidding the use of variables in logical forms, in order not to compromise the Montagovian model-theoretic doctrine of the nonessential nature of logical forms in semantics. The relation of this work to variable-based and variable-free approaches in the present sense is discussed by Dowty (1993). This work is discussed in **Categorial Grammars: Deductive Approaches**.

The emphasis on this other path was on explanatory adequacy, in the sense of reducing the degrees of freedom in the theory, and on parallels between rules of syntax and semantic interpretation. There was a widespread tendency toward Lexicalization of grammar, and an active involvement of computational linguists and psycholinguists in defining the theory of grammar.

These two approaches coexisted, fairly amicably though not always with complete mutual understanding, for a number of years, assimilating each other's discoveries from time to time. There are clear signs that these two programs will soon converge on a unified explanatorily adequate theory.

Variables in the Theory of Syntax

Transformations are defined by Chomsky in terms of a Structural Analysis and a Structural Change. The first of these defines the set of phrase-structure trees to which the transformation may apply in terms of a Proper Analysis, which can be thought of as defining sequences of category labels obtainable by making a 'cut' across all branches of the tree. The Structural Change then specifies a rearrangement of the elements of the proper analysis in terms of elementary transformations of substitution, deletion, and adjunction. For example, the phrase structure tree underlying passive sentence *Johnnie was loved by Frankie* is obtained from the phrase structure tree that also underlies the active *Frankie loved Johnnie* by an (optional) transformational rule that might be written (simplifying various original notations) as follows:

$$
\begin{array}{llllllll}
(1) & \text{SA:} & NP_1 & Aux & V & NP_2 & \Rightarrow & \\
 & \text{SC:} & NP_2 & Aux & be & en & V & (by\ NP_1)
\end{array}
$$

(The realization of both active and passive sentences involves further applications of an Affix Hopping transformation.) Similarly, the transformation that derives relative clauses such as *(the man) who likes Frankie*, (*the man) who Frankie likes* and *who Frankie said Johnnie likes* from canonical clauses

might be written (again simplifying) as the following *Wh*-movement transformation, where *Wh* is the category of relativized elements like *who(m), to whom*, etc.:

(2) SA: *X* *Wh* *Y* *Z* ⇒
SC: *Wh* *Y* *X* *Z*

Unlike the former rule (1), rule (2) makes use of a variable *Y*, which ranges over sequences of categories corresponding to such nonconstituent prefixes as *Frankie likes* and *Frankie said Johnnie detests* among infinitely many others, including the null or empty string. (It is worth noting that there is a certain obscurity in transformational rules like the above as to what structure relates *X, Y*, and *Wh*. This obscurity is only partly corrected by certain global conditions, such as that deletions should be recoverable and that transformations do not change meaning, in the sense that it is not clear how the rule itself embodies or imposes the latter condition.)

As Chomsky himself pointed out, rule (2) overgenerates, because the variable *Y* can also match category sequences underlying clause prefixes like *Frankie likes Johnnie and* to yield ungrammatical relative clauses such as the following:

(3) (a man) *who Frankie likes Johnnie and

Chomsky accordingly proposed an A over A condition on rule (2), forbidding the movement of *Wh*-elements of type NP (PP, etc.) out of elements of type NP (PP, etc.). Ross and others went on to identify an extensive catalog of specific Constraints on *Wh*-movement, including the Coordinate Structure Constraint, the Fixed Subject Condition, and the cynically named Clause-Non-Final Incomplete Constituent Constraint, which respectively exclude the following examples, which would otherwise be allowed by (2):

(4a) (a man) *who Frankie likes and Johnnie detests him
(4b) (a man) *who Frankie said that detests Johnnie
(4c) (a man) *who Frankie proved to that she could sing

Many of these constraints had a highly specific stipulative character. For example, the Coordinate Structure Constraint, which rules out (3) and (4a), carries an Across-the-Board exception to allow (5a) and a further Same-Case condition on the exception to forbid (5b):

(5a) (a man) who Frankie likes and Johnnie detests
(5b) (a man) *who Frankie likes and detests Johnnie

Much subsequent work within the Chomskean mainstream followed, attempting to identify significant generalizations over such constraints.

Meanwhile, Kimball, and Peters and Ritchie had shown that, once transformations as conceived by Chomsky were fully specified formally, they were of a class characterizing the highest level of the language hierarchy, level 0 or the recursively enumerable languages, equivalent in automata theoretic terms to a Universal Turing Machine. This also led to a search for linguistically plausible ways of restricting transformations to at least generating decidable recursive sets.

However, a far more important effect of this work was to focus renewed attention on the importance of making grammars fully formal, and on the danger of inadvertently allowing huge expressive power in the theory. (Even the Type 1 (Context-Sensitive) subset of the decidable recursive sets include members with wildly unnatural properties, such as the nonconstant-growth language a^{2^n} (discussed by Joshi). The result was to revive interest in the more general question of identifying as low a bound as possible on the expressive power required to capture the syntax of natural languages with strong adequancy.

The answer to that question is the same as for an artificial language such as a programming language, namely: whatever power is required to support the Compositional Semantics of that language. This is not terribly helpful, since we have a very limited formal grasp of natural language semantics. However, the fact that the syntax of programming languages and logics (which include languages capable of expressing any Turing machine-computable function) is essentially entirely context-free caused a number of researchers to question the wisdom of starting with such a powerful class of rules as transformations in the first place. Such observations revived interest in the question of exactly where on the language hierarchy natural languages fell, and in the question of whether there were other, possibly much less expressive, grammar formalisms from which the constraints of TG would follow without stipulation. Much of this work had the effect of eliminating the use of variables in the transformational sense, although it is also stressed that mere elimination of such variables from the transformational account is not of itself enough to limit the capacity of TG to generate all recursively enumerable sets. Peters and Ritchie's proof still goes through, as Friedman points out.

Moves to Restrict Expressive Power

A key observation due to Emonds and Kimball was that *Aspects*-style transformations came in two distinct varieties that they distinguished respectively (and slightly nonoverlappingly) as 'structure-preserving' or 'cyclic,' and 'root' or 'last-cyclic.' The former class included transformations such as passive, (1),

that apply to elements local to the domain defined by the Transformational Cycle (essentially that of the tensed verb), and were characterized by moving things to positions that were already licensed by rules in the grammar – for example full passives like *Frankie was loved by Johnnie* are homomorphic to nonpassive predicatives like *Frankie was serious by inclination*. For Kimball at least, the former class was also identified by not involving the use of variables. (Emonds classified wh-movement as structure-preserving, involving a base-generated COMP.)

These observations suggested a number of simplifications to TG. First, if the first kind of transformation was local to a headed domain, and only produced structures that were already captured in the base grammar, then the corresponding constructions might as well be handled there via Base-Generation, without the involvement of such a potentially more powerful class of rules. As a corollary, the involvement of lexically headed local domains suggested that this base-generative component could be lexicalized. Either tactic would have the advantage of eliminating the unclarity in rules like (1) as to exactly what structure was implicated in the output of the rule. These implications were influentially taken up by Brame and Bresnan.

Second, these observations focused attention more narrowly on constructions like *Wh*-movement and rules involving variables like (2). While Emonds' particular characterization of them as structure-preserving rules made use of transformational variables, and appeared to stretch the definition of structure-preservation undesirably, it also suggested that a base-generative treatment should be possible. (This is a suggestion that Chomsky partly took up in proposing a cyclic analysis, and which Bresnan opposed. However, variables are still used under Chomsky's proposal to define a 'subjacency' constraint to keep the transformation bounded, rather than explicit lexicalization.)

In this connection, it is interesting that the computational linguists Thorne, Bratley and Dewar and Woods, in line with a suggestion implicit in Kuno, had already proposed a form of base-generative grammar embodied in a type of parser that Woods named the Augmented Transition Network (ATN). The ATN grammar used a surface grammar of English comprising context-free rules represented as finite-state automata whose state transitions were associated with operations of a fixed set of registers or storage locations representing the underlying deep structure or meaning representation. Since these operations could be arbitrary LISP expressions, the ATN was in principle Turing Machine-Equivalent. However, the fact that its operations were limited to a fixed set of registers directly embodied the structure-preserving property of cyclic transformations such as passive (1), as Bresnan pointed out. Moreover, the transformations that involved sequence variables, like *Wh*-movement (2), involving nonadjacent elements, were handled in a strikingly novel way by a register computation. At the point in the base-generative recursive transition network where a 'moved' element such as a relative pronoun was encountered, a marker was transferred to a special register called HOLD. The rules defining the nounphrase and other 'movable' argument types were augmented with an extra transition allowing a marker of that type to be retrieved from the HOLD register in lieu of an *in situ* argument. One of the attractions of this computational approach is that it made the process of parsing transformations entirely incremental: the work of transformations was done on the fly, at the point in the left-to-right process where the information relevant to the transformation became available.

This mechanism anticipated the interpretation of movement in terms of coindexation in later Transformational Grammar, and was seen by Woods himself as offering a way to constrain *Aspects*-style transformations. The ATN led to a number of extensions of of base-generative grammars using structural Unification, following a proposal by Kay, including Bresnan and Kaplan's Lexical-Functional Grammar (LFG) and Pollard and Sag's Head-driven Phrase Structure Grammar (HPSG). However, unification like TG makes essential use of variables ranging over structures, and it is easy to write dismayingly simple unification grammars that generate non-constant-growth languages like a^{2^n}, as Berwick and Weinberg showed.

However, Woods made another, orthogonal, suggestion about how the power of grammars could be limited when he suggested that the predominantly nesting behavior of multiple dependencies could be captured by making the ATN HOLD register a stack, or push-down store, from which more recently stored elements must be retrieved before earlier ones can be accessed. Since a context free surface parser already uses a stack to control recursion, this restriction did not in itself limit the Turing-machine power of ATNs. Nor was it clear how to handle the known exceptions to dependency nesting. However, it was a strikingly simple mechanism for constraining movement without the use of structural variables that has many echoes in the accounts that followed

Nearly Context-Free Grammars

One early response to the renewal of interest in low-expressive power grammars for natural language was Gazdar's Generalized Phrase Structure Grammar (GPSG), which showed that almost all of the facts about English that had appeared to call for a

transformational analysis, including agreement, the structure-preserving or bounded constructions, wh-movement, and at least some varieties of deletion under coordination, could be captured using entirely context-free rules, on the assumption that grammatical categories like NP and VP were bundles of Attribute-ValuePairs, where attributes were constants such as *number* and whose values were constants such as *plural* or variables over such constants, rather than the arbitrary structures of full unification grammar. Crucially, one such attribute, called SLASH, whose value could be a category name like NP, identified the category in question as having an argument of that category extracted from the structure it dominated. Crucially, the SLASH feature could pass from the parent node of a rule to an offspring node. Thus as well as the standard rule (6a) expanding S, GPSG allowed rule (6b), meaning that an S with an extracted NP could be rewritten as an NP and a VP with an extracted NP:

(6a) *S* → *NP VP*
(6b) *S/NP* → *NP VP/NP*

(The attribute-value pair ⟨SLASH, *NP*⟩ is written */NP*. CPSG nonterminals such as *VP/NP* denote constituents of type *VP*, and should not be confused with the category written the same way in Categorial Grammar, which is the type of a function *into VP* – that is, that of a transitive verb.) Further rules either introduce such slashes, as in (7a), pass them on to arguments of the VP, as in (7b) and (7c), or realize the SLASH feature as either the empty string, as in (7d), or as a trace.

(7a) *N* → *N Wh S/NP*
(7b) *VP/NP* → V_{14} *NP/NP*
(7c) *VP/NP* → V_{15} *S/NP*
(7d) *NP/NP* → ε

(V_{14} and V_{15} are preterminals for transitive and sentential complement verbs, respectively.) This grammar allows derivations such as the following:

(8a)

(8b)

On the assumption that coordination was a rule that could combine any categories of the same type, and that S, VP, and S/NP were all distinct types, GPSG captured the Coordinate Structure Constraint on extraction, the Across-the-Board Exception to that constraint, and the Same-Case Condition on that exception, together with the corresponding facts about rightward extraction under coordination, among other significant generalizations. For English, at least, it went a long way toward providing a full grammar of long-range dependency without the use of transformations or transformational variables.

However, there were known phenomena involving multiple dependencies that made it seem highly likely that more power would be required. One was the existence of constructions with multiple dependencies. In particular, so-called Verb-raising Constructions in Germanic presented examples of constructions that obligatorily **crossed** arbitrary numbers of long-range dependencies between infinitival verbs and their arguments in verb-final constructions. Such crossing dependencies were known to be beyond the strong generative capacity of CF grammars. As in the case of the ATN HOLD register, it was not immediately clear how to generalize the GPSG SLASH feature so as to allow multiple dependencies without increasing expressive power too far.

Meanwhile, two other ways of generalizing context-free grammars while retaining low expressive power had been proposed within computational linguistic frameworks. Tree-Adjoining Grammar (TAG), first proposed by Joshi, Levy, and Takahashi, was extended by Joshi and Levy to cover unbounded dependencies using a mechanism that amounts to base-generated coindexation. TAG takes two types of elementary tree as its building blocks. The operation of Substitution combines initial trees representing the local domain of a head such as a verb or a noun.

The operation of Adjunction combines auxiliary trees with (possibly derived) trees and is the distinctive operation of the formalism. An example of topicalization will show the general idea (the notation is from a later, lexicalized version of theory). An initial tree α_1 defines one possible local domain for a transitive verb *like*, in which the object is in topic position and is coindexed with an empty extraction site. An auxiliary tree β_1 represents the domain of the verb *thinks*. Other initial trees $\alpha_{2,3}$ are the NP arguments of the verbs, and combine by substitution. The crucial part of the derivation lies in the operation of adjunction, which has the effect of 'splitting' the S node in α_1, and 'Chomsky adjoining' β_1, 'stretching' the base-generated dependency between the topicalized object and the embedded verb:

(9)

The following derived structure, in which the adjoined β_2 is circled, results:

(10)

Since this derived tree is of an appropriate kind for further adjunctions of auxiliary trees like β_1, the unbounded nature of topicalization and relativization is captured. The adjunction operation is the principal source of the trans-context-free expressive power of TAG.

A second generalization of lexicalized context-free grammar, based on Categorial Grammr (CG) was called **Combinatory Categorial Grammar** (CCG). In CCG, syntactic heads are associated with a functional type defining their local domain. For example, the transitive verbs *likes* and *thinks* are written as follows, defining them as function from NP and S, respectively, on the right into functions-from-NPs-on-the-left-into-S (these slashes should not be confused with the GPSG SLASH feature notation defined above):

(11a) likes := $(S\backslash NP)/NP$: *likes*'
(11b) thinks := $(S\backslash NP)/S$: *thinks*'

Since all linguistic categories in CCG are syntactically defined only as to their type, rather than as a syntactic structure, CCG categories, rules, and derivations are accompanied by a logical form associated via a colon operator. Logical form is the only representational level that is countenanced in CCG

The proposal behind CCG was to use a single category such as (11a) to determine **both** the local dependency between a verb an an *in situ* object **and** the unbounded dependency between that verb and an extracted object such as a topic or relative pronoun. (Ades and Steedman explicitly related this idea to that of using the 'same' stack to mediate recursion and unbounded movement in an ATN.)

In order to capture unbounded dependency, besides the standard CG context-free operations of (forward and backward) function application, such as (12a), CCG includes rules of Functional Composition, such as (12b), and rules of Functional Substitution/Connection (first proposed by Szabolcsi for the analysis of Parasitic Gaps), such as (12c), in conjunction with lexical (forward and backward) type-raising of all argument categories, as in (12d), including relative pronouns, as in (12e), (again, logical forms are included, using the notation of the λ-Calculus with concatenation as application):

(12a) *Forward application (>):*
$X/Y : f\ Y : a \rightarrow X : fa$
(12b) *Forward composition (>**B**):*
$X/Y : f\ Y/Z : g \rightarrow X/Z : \lambda z.f\ (gz)$
(12c) *Forward crossed substitution* (>**S**):
$(X/Y)\ /\ Z : f\ Y/Z : g \rightarrow X/Z : \lambda z.fz\ (gz)$
(12d) *Nominative lexically type-raised NP category:*
we := $S\ /\ (S\backslash NP)$: $\lambda p.p$ *we*'
(12e) *Relative pronoun category:*
who(m), that := $(N\backslash N)\ /\ (S/NP) : \lambda p \lambda n \lambda x.(nx) \wedge (px)$

(Other syntactic operators corresponding to structure-preserving transformations have been proposed by Bach and Jacobson.) Although the CCG notation for rules uses variables *X, Y* over syntactic categories, this is a nonessential use as an abbreviation over a finite set of single category types, distinct from the transformational use of variables. And although

the λ-terms of logical form use variables, these are not **syntactic** variables in the relevant sense. Again, the general idea can be understood from the following derivations, in which rules of (forward and backward) application are indexed with unadorned arrows, (forward) composition is indexed $>\mathbf{B}$, (forward, lexical) type-raising is marked $>\mathbf{T}$:

(13)
$$\begin{array}{cccc}
\text{man} & \text{that} & \text{Frankie} & \text{likes} \\
\overline{N} & \overline{(N\backslash N)/(S/NP):} & \overline{S/(S\backslash NP):}\,{>}\mathbf{T} & \overline{(S\backslash NP)/NP:} \\
man' & \lambda p\lambda n\lambda x.(nx)\wedge(px) & \lambda f.f\ frankie' & \lambda x\lambda y.likes'xy \\
 & & \multicolumn{2}{c}{\overline{S/NP : \lambda x.likes'x\ frankie'}\,{>}\mathbf{B}} \\
 & \multicolumn{3}{c}{\overline{N\backslash N : \lambda n\lambda x.(nx)\wedge(likes'x\ frankie')}\,{>}} \\
\multicolumn{4}{c}{\overline{N : \lambda x.(man'x)\wedge(likes'x\ frankie')}\,{<}}
\end{array}$$

(14)
$$\begin{array}{ccccccc}
\text{man} & \text{that} & \text{Johnnie} & \text{says} & \text{Frankie} & \text{likes} \\
\overline{N} & \overline{(N\backslash N)/(S/NP):} & \overline{S/(S\backslash NP):}\,{>}\mathbf{T} & \overline{(S\backslash NP)/S:} & \overline{S/(S\backslash NP):}\,{>}\mathbf{T} & \overline{(S\backslash NP)/NP:} \\
man' & \lambda p\lambda n\lambda x.(nx)\wedge(px) & \lambda f.f\ johnnie' & \lambda x\lambda y.say'xy & \lambda f.f\ frankie' & \lambda x\lambda y.likes'xy \\
 & & \multicolumn{2}{c}{\overline{S/S : \lambda x.say'x\ johnnie'}\,{>}\mathbf{B}} & \multicolumn{2}{c}{\overline{S/NP : \lambda x.\text{likes}'x\ frankie'}\,{>}\mathbf{B}} \\
 & & \multicolumn{4}{c}{\overline{S/NP: \lambda x.say'(likes'x\ frankie')johnnie'}\,{>}\mathbf{B}} \\
 & \multicolumn{5}{c}{\overline{N\backslash N : \lambda n\lambda x.(nx)\wedge(say'(likes'x\ frankie')\text{johnnie}')}\,{>}} \\
\multicolumn{6}{c}{\overline{N : \lambda x.(man'x)\wedge(say'(likes'x\ frankie')\text{johnnie}')}\,{<}}
\end{array}$$

The composition rules (in particular the fact that they can apply to n-ary functions up to some small fixed n, and that 'crossed' composition rules that mix the directionality of the input functions are allowed) are the principal source of the trans-context-free power of CCG.

A further formalism called Head Grammar (HG) comes from Pollard, who generalized CFPSG using a distinctive 'wrapping' operation (quite unrelated to the WRAP rule of certain varieties of CCG) to handle multiple dependencies. Pollard's wrapping rule is closely related to the notion of adjunction in TAG, and is the main source of its trans-context-free power.

Joshi and Steedman showed that TAG and CCG provided dramatically simple accounts of crossing dependencies in Dutch and related languages, which had by then been proved to be not even weakly context-free, thereby showing that both formalisms were of strictly greater than context-free power. Joshi, Vijay-Shanker, and Weir in a series of papers from 1985 to 1994, showed that all three of these grammar formalisms were weakly equivalent to each other and to Linear Indexed Grammar (LIG), a restricted form of Indexed Grammar in which a single stack-valued feature can be passed from a single nonterminal on the left-hand side of a production rule to a single daughter on the right-hand side, optionally accompanied by the pushing or popping of the stack-value. The proof of Vijay-Shanker and Weir (1994) shows weak equivalence by proving the following sequence of containment relations between the sets of languages generated by CCG, LIG, HG, and TAG:

(15) CCL $\subseteq$ LIL $\subseteq$ HL $\subseteq$ TAL $\subseteq$ CCL

Vijay-Shanker also showed that the characteristic automaton for this class of grammars and languages was a generalization of the Push-Down Automaton (PDA), called the Embeded Push-Down Automaton (EPDA). Weir showed on this basis that there was an infinite hierarchy of languages, grammars, and automata, of strictly less than context-sensitive power, characterizing what Joshi called Mildly Context-Sensitive Languages, of which the above class was the least powerful member after CF languages themselves. A number of results including polynomial ($O(n^6)$) worst-case parsing complexity for all four formalisms follows from the equivalence proofs, which are constructive. The significance of this result is that standard parsing algorithms based on dynamic programming can be applied.

A word of caution is in order in interpreting these important results. Weak equivalence does not entail strong equivalence. Even strong equivalence between formalisms does not mean that they are indistinguishable for linguistic purposes. For example, because in CCG *in situ* arguments are handled with the same slash as extracted ones) there is a very simple construction (given by Steedman), in which the multiple arguments of a function category are represented by a single stack-valued feature, which will yield a strongly equivalent LIG for any CCG. However, the LIG that results from, say the CCG fragment for the Dutch construction, is quite counterintuitive. Gazdar in fact concluded his attempt to analyze the construction by conjecturing that there could be no strongly adequate LIG for it, and that the much greater expressive power of full IG would be required. It seems in short that CCG and TAG are better-adapted to the expression of the relevant generalization.

There are other linguistically and computationally significant differences to bear in mind between

these formalisms. For example, the Principle of Combinatory Type-Transparency of Combinatory Categorial Grammar (CCG) guarantees that the syntactic composition and type-raising operations illustrated in (13) and (14) always correspond to semantic function composition and type-raising. It follows that a semantic interpretation is always immediately available when any constituent is formed. By contrast, the operation of adjunction in TAG sometimes corresponds to semantic composition, as in (9), but sometimes to application, as in the formation of the corresponding simple complement '*Johnnie thinks Frankie likes Manny*,' (which is formed by adjunction at the root node, rather than substitution).

Nor does adjunction fully implement CCG composition. Strongly adequate capture of certain extractions such as the following analog of (10) that in CCG are accomplished by exactly the same variety of composition as in (13) and (14) have been argued to require a generalization of basic TAG to the tree-local version of multicomponent TAG:

(16) (The man) that Johnnie said Frankie liked a picture of

These differences may present problems for any straightforward implementation of incremental semantic interpretation in TAG parsing. It also remains unclear whether the natural generalizations of CCG are the same as those of TAG.

However, these differences are less important than the fact that both formalisms are nearly context-free, in the sense that they reside at the lowest level of expressive power above context-free that has yet been identified among the mildly context-sensitive languages identified by Joshi.

Conclusion: Toward a Unified Theory of Grammar

The crucial operations of adjunction in TAG, and Composition in CCG superficially resemble the Generalized Transformations (sometimes called Double-Based Transformations) of Chomsky's first version of Transformational Grammar, as Frank has pointed out, in that they apply to combine two grammatical objects. However, they differ crucially from the original generalized transformations. First, they are not Structure-Dependent Rules: their operation is entirely conditioned by the type of a single constituent node to which they apply. Second, they do not create domains over which singulary movement transformations (whether cyclic or not) can create new dependencies. Instead they merely project the dependencies that have been defined once and for all in the lexicon. These dependencies include unbounded dependencies, defined either via elementary trees like ($9\alpha_1$) in the case of TAG, or via the logical form of a higher-order category like that of the relative pronoun in (12d) in CCG.

It is interesting in this connection to compare the weakly LIG-equivalent theories with the modern version of TG, as defined in the Minimalist Program (MP) of Chomsky, which continues to define long-distance dependencies with unlexicalized singulary transformational rules of movement explicitly or implicitly using variables. Under Stabler's definition of Minimalist Grammar (MG), these have been shown by Michaelis to be equivalent to a more powerful version of TAG called Set-Local Multicomponent Tree-Adjoining Grammars (SMCTAG). While such grammars are LCFRSs with such desirable properties as constant-growth, they are very expressive, and can generate such unnatural non-LILs as the 'quadruple copy language' *WWWW*. It remains unclear whether or not such additional expressive power is needed for any truly syntactic phenomenon of human language, but in either case it seems clear that all of the theories considered here will soon converge on a single level in an extended Language Hierarchy, and perhaps even on a single unified theory of grammar.

Syntactic Variation

M Meyerhoff, University of Edinburgh, Edinburgh, Scotland

Approaches to Studying Syntactic Variation

Broadly speaking, there are three ways to study variation in syntax. The first is to simply describe the variation as alternative syntactic structures expressing fundamentally 'the same thing.' The second is to analyze the variation as the reflex of an alternation between different underlying grammatical rules. The third is to motivate the variation as a reflex of cognitive or functional constraints operating on speakers and in an interaction. Each of these tends to be associated with somewhat different research methods, but the approaches can be combined in a single investigation. At different stages in their enquiry, researchers might first describe the possible variants, and then expand the basic description to explore a variety of possible constraints on those variables. Depending on the analyst's predisposition and their training, the constraints they explore may be other formal linguistic factors, or they may be functional or discourse constraints.

All three methods often deploy quantitative evidence in support of their analysis and this use is increasingly the norm as large corpora become available for a wide variety of languages and software improvements make such corpora easier to access. However, it is also possible to find accounts of syntactic variation that are based on a single researcher's intuitions. Impressionistic or intuitive descriptions of syntactic variation serve a useful purpose as 'book marks' when they appear in descriptions of lesser spoken languages (the primary goal of the analyst may be to provide a grammatical outline of an endangered language before it disappears). As such, they can be valuable indicators of places where a grammar is not well understood, and encourage subsequent researchers to undertake productive new work. Such impressionistic or idiosyncractic descriptions are, however, of questionable use and validity when they constitute the sole evidence for, say, a subtle, theory-internal point. As the examples to be discussed in this article will show, syntactic variation is deeply intertwined with constraints from many other linguistic domains (and sometimes social factors, too). Consequently, analyses based on decontextualized, constructed sentences leave many important factors dangerously under-determined.

This article provides a brief overview of three schools of research that are concerned with accounting for variability in syntactic structures. Analyses of syntactic variation based on impressionistic data will not be examined because of the problems just mentioned. Neither will examples of developmental syntactic variation (variation as consequence of a child learning her L1; adult attrition of an L1; L1 interference on a late acquired L2). These issues are all covered in other articles. This article outlines some key concepts in the study of syntactic variation as practiced by variationist sociolinguists. It proceeds to compare and contrast formal and functional analyses along those key dimensions.

Key Variationist Concepts

Two key concepts for the study of syntactic (as for any other) variation are the definition of a variable, and the notion of inherent variability in the grammar. A linguistic variable is an abstract notion that is realized by multiple ways of saying the same thing. It is clear with most phonological variables that variants are semantically equivalent (*left wing* means the same as *lef' wing*), but semantic equivalence may be fuzzier with syntactic variables since syntax, semantics, and discourse structure are all so intimately connected. It is now widely agreed that rough semantic or discourse function equivalence is an appropriate standard for including a syntactic variable in a study.

Inherent variability replaces the notion of 'free variation.' Formerly, if it was unclear when speakers chose one variant over others, linguists described the variants as being in free variation. But Uriel Weinreich and William Labov showed that 'free' variation is an under-analysis of the data. All variables subjected to rigorous study show some linguistic or social constraints on the distribution of their variants. 'Free variation' has been superseded by the idea that variability is an inherent property of the grammar. Consequently, the linguist's job is as much to describe variable structure as invariant structure.

Descriptive and Variationist Perspectives on Syntactic Variation

Differences between the syntax of spoken and written varieties of a language are becoming more widely recognized. Computerized corpora and the search/extraction techniques associated with these have played a role in defining these interests, as too have advances in speech technology, in which systems are

increasingly expected to be able to simulate natural dialogue.

Pioneers in the description of syntactic variation in use, such as Jenny Cheshire, Jim Miller, and Andrew Pawley, have come to the field from a range of backgrounds – variationist sociolinguistics, structural linguistics, and fieldwork in non-standard or lesser spoken languages. Careful attention to the patterns emerging from what has sometimes been seen as 'performance errors' in natural speech, enable linguists to do three things:

1. recognize aspects of the grammar of a language that had previously been ignored (e.g., Cheshire's work on lone *when* clauses, Pawley's on clause-initial ellipsis);
2. identify changes in progress (e.g., Rickford, and Britain on *as far as… is concerned*);
3. contribute to the development of theory in grammaticalization (e.g., Miller's work on the perfect), or formal syntax (e.g., Adger and Smith's work on subject-verb agreement and negative concord).

Most quantitative sociolinguistic studies of syntactic variation are fundamentally descriptive; their results are presented so as to engage most directly with general principles about the diffusion of variation in a speech community. There is some question about whether syntactic variables are constrained by the same kinds of sociolinguistic principles as phonological variables are. The real time record may make it clear that a particular syntactic change is in progress, as e.g., Sankoff and Laberge showed with respect to cliticization of the irrealis marker *bae* in the Tok Pisin verb phrase. However, the change may not be associated with the kind of steady stratification by speaker age that phonological changes in progress are associated with. This may be because syntactic innovations sometimes have a lexical quality (and we add items to our vocabulary throughout our lives).

Another finding relevant to variationist sociolinguistics is the typical absence of stratification by social class or social network for syntactic variables that represent changes in progress. It is not clear why this lack should be true, but may have something to do with how (in)accessible syntactic structure is to the average person for meta-linguistic comment compared to pronunciation.

Competing Grammars Approach to Syntactic Variation

Connections between the study of syntactic variation and formal theories of syntax have been explored in most depth by researchers working within formal, generative frameworks. Anthony Kroch's work has been influential in this field. Kroch undertook a quantitative analysis of variation in word order in French and English and in possessor marking in Portuguese. He concluded that the diachronic pattern of variation supported two propositions: first, the constant rate hypothesis, i.e., changes move through both favoring and disfavoring contexts at a steady rate, and second, variation results from competition between different grammars.

The second proposition is attractive to formal linguists because it essentially removes variation from the grammar (cf. inherent variability), arguing instead that when a speaker uses different word orders, they are drawing on different underlying grammars. In the terminology of Minimalism, for instance, a feature might be strong in one grammar and weak in another; this shift will lead to differences in overt movement, so speakers may produce functionally equivalent structures that differ in the order of their constituents. This analysis runs counter to the notion that variation is inherent to the grammar; under this account, syntactic variation is essentially the same as code-switching for the multilingual speaker.

An important feature of Kroch's work has been the emphasis on triangulation. It may be possible to model a single variable within a Minimalist theory of syntax, but the most careful work within this paradigm makes its case for competing grammars by showing that multiple, independent syntactic variables converge in just the way a particular syntactic theory would predict.

In her work on syntactic variables in a contact variety of French, Ruth King argues that borrowed lexical items carry with them specific syntactic structures, and that this (rather than language mixing) is what accounts for the unique behavior of prepositions in Newfoundland French. Though King works within a generative framework, in principle her conclusion about the lexical basis of syntactic variation and change is theory-neutral and might be compatible with other formal theories such as HPSG.

Functional Perspectives on Variation

Like variationist sociolinguistics, functional syntax does not accept the competence/performance distinction. As sociolinguistics generally does, functional syntax uses data from natural corpora rather than elicited production or attitudinal data. Functionalists account for variation in terms of general cognitive principles, or specific interactional factors emerging in different communicative contexts. Speakers' attitudes, stance, intersubjectivity, information flow, and turn-taking are all central components in a functionalist account of grammar. Like

some formal syntax approaches to variation, a functionalist account may actually remove variation from the domain of grammar, and conclude that subtle differences involving the face-to-face situation, topic of conversation or state of mind of the speaker exhaustively account for any variation observed. A functionalist approach differs fundamentally from variationist sociolinguistics and formal linguistics in that even though it may concede that variability is an inherent property of language (perhaps by virtue of the inherent dynamism of interaction and language in use), it posits no underlying or underived structure. One implication of this is that there is nothing analogous to the (socio)linguistic variable in functional syntax.

Notwithstanding, connections between grammaticalization theory and functionalist approaches to syntactic variation abound and grammaticalization theory is open to a diachronic sense of derivation, even if it rejects the notion of synchronic derivation.

Conclusion

Many syntactic phenomena that would (under some perspectives) be seen as variables, in fact defy a purely formal or purely functional account. The distribution and form of overt and null arguments (which many formal linguists have argued is a pragmatic phenomenon and not syntactic at all) shows a cross-linguistic tendency to be sensitive to quintessentially functional factors (e.g., recency or salience of mention) but researchers may model the variation within a formal framework. Conversely, the motives postulated for formal reanalysis are often functional, e.g., ambiguity causing speaker and hearer to associate an utterance with different underlying structures. Some of the most interesting work on syntactic variation (and change) embraces multiple causes, and argues that the direction of change is best predicted when underlying grammar and functional considerations converge.

Syntax of Words

R Lieber, University of New Hampshire, Durham, NH, USA

© 2006 Elsevier Ltd. All rights reserved.

Theoretical approaches to morphology in the generative tradition can be characterized by the tendency to either reject syntax explicitly as a theoretical model or embrace syntax and evolve in tandem with it. It seems safe to say that the study of inflection and word formation has benefited greatly from this tension, in that it has resulted in a greater understanding of what morphology has in common with sentence structure and what makes it distinct.

This tension between syntactic and antisyntactic views of morphology can perhaps be traced back to American structuralism, in which Hockett (1954) distinguished three models of morphology: item and arrangement (IA), item and process (IP), and word and paradigm (WP). In the IA model, morphemes within words are ordered both linearly and hierarchically, much as words are within a syntactic analysis. IP models, in contrast, eschew linear and hierarchical ordering; instead, complex words are derived from bases to which morphological rules or processes are applied. WP, mentioned only in passing by Hockett but later developed in more detail by Matthews (1972), also dispenses with linear order and hierarchical structure, treating words within a matrix of cross-classifying characteristics such as person, number, and tense. Whereas syntactic treatments of morphology within the generative tradition are direct descendants of the structuralist IP model, antisyntactic theories bear much in common with IP and WP conceptions.

Within the generative tradition, inflection was from the first treated as a syntactic phenomenon, with Affix Hopping being among the earliest of Chomsky's (1957) transformations. The transformational analysis of other forms of word formation followed shortly thereafter, with Lees's (1963) analysis of nominalizations as a transformational phenomenon; in this sort of analysis, transformations apply to a sentential base such as (1a) to create the corresponding nominalization in (1b):

(1a) the Romans destroyed the city
(1b) the destruction of the city by the Romans

The transformational line of analysis was pursued within the framework of Generative Semantics; in this framework, which associated deep structure with semantic representation, a seemingly monomorphemic word such as *kill* could be derived from a syntactic structure

[NP [CAUSE [BECOME [NOT [NP ALIVE]]]]]

by means of a Raising transformation (McCawley, 1973). Levi (1978) is a relatively late and quite sophisticated treatment of compounding and nominalization within this tradition.

As a reaction to the Generative Semantics framework, Chomsky's (1970) 'Remarks on nominalization' signals both a break with the syntactic treatment of word formation and the true birth of generative morphology as a separate theoretical field. Indeed, early generative treatments of morphology (Halle, 1973; Jackendoff, 1975; Aronoff, 1976) are careful to distinguish morphology from syntax as a separate component with a distinct set of rules and principles. This independence was proclaimed in the Lexicalist Hypothesis (also called the Lexical Integrity Hypothesis), stated in its strongest form by Lapointe (1980), namely that syntactic rules cannot refer to morphological categories or features. Aronoff's (1976) seminal work on word formation is in line with the Structuralist IP tradition, with word formation rules (WFRs) applying to bases to derive complex words.

Even among avowed lexicalists, however, rules of word formation soon came to resemble rules of syntax. Roeper and Siegel (1978) was an early attempt to account for the structure and interpretation of English synthetic compounds such as *truck driver* by means of a lexical transformation; although such a transformation operated within the confines of the word formation component, it generated synthetic compounds by moving a postverbal complement into a preverbal position. The transformation is shown in Figure 1.

Similarly, Lieber (1980), Williams (1981), and Selkirk (1982) all proposed lexicalist treatments of word formation that borrowed the form of rules – this time phrase structure rules – from syntactic theory. Selkirk (1982: 66), for example, proposes word structure rules for English such as:

(2a) $A \rightarrow N\ A^{Af}$
(2b) $N \rightarrow A\ N^{Af}$

These theorists also made use of the syntactic term 'head,' giving it a uniquely morphological definition (DiSciullo and Williams, 1987: 26):

[[empty] + verb + affix] [$_{X+N}$ + word] W ==> [[+word] + verb + affix] W
1 2 3 4 5 4 2 3 Ø 5

Figure 1 Compound rule (Roeper and Siegel, 1978: 209).

Definition of 'head$_F$' (read: head with respect to the feature F): The head$_F$ of a word is the rightmost element of the word marked for the feature F.

Although these rules and principles range over a set of categories (X^0, Af) that are not syntactic, form structures that are distinct from those of syntax, and refer to linear order (e.g., 'rightmost' in the definition) in a way that syntactic rules do not, the rule types themselves are clearly syntax inspired.

Taking place at roughly the same time as these early phrase structural theories, advances in phonology in the form of autosegmental theory led to structural treatments of nonlinear and nonconcatenative morphology. Significant in this tradition is McCarthy's (1979) analysis of Semitic root and pattern morphology, Marantz's (1982) treatment of reduplication, and Lieber's (1984) analysis of consonant mutation. Marantz, for example, proposed that reduplication is affixation, with the reduplicative affix taking the form of a bare skeleton composed of consonants and vowels that are filled in by autosegmental spreading; these analyses allowed nonconcatenative morphology to be subsumed under phrase structural theories of word formation.

Early lexicalist theories of generative morphology led in the early 1990s to a veritable war concerning the relationship between syntax and morphology, with positions ranging from the militantly lexicalist to the staunchly syntacticalist; the debate hinged on whether morphology should constitute a distinct module of the grammar wholly segregated from syntax or should be completely integrated into the syntax, subject to syntactic rules. Anderson's (1992) *A-morphous morphology* can be placed at the lexicalist end of the scale. Rejecting the notion of morpheme entirely, Anderson proposed a theory in which word formation processes apply to lexical items, the output being morphosyntactically complex but internally unstructured items; once the notion of morpheme was dispensed with, so too did linear order and hierarchical structure fall by the wayside. Beard's (1995) Lexeme Morpheme Base Morphology is another framework that rejects a syntactic approach to morphology.

In contrast, Lieber (1992), working within the Principles and Parameters framework of syntax and following the ideas of Sproat (1985), proposed that morphology was nothing but syntax: if the X-bar theory of phrase structure was modified in small ways, the parameters determining the order of head-complement, head-specifier, and theta role assignment could be set just once per language, thus predicting the sort of word formation we might expect to find in a language. Deviations from the predicted order were dealt with in the morphology, as in the syntax, with movement rules. For example, in English, complements follow heads; a movement analysis is therefore required to derive the complement-head order that we find in synthetic compounds such as *truck driver.*

Both extreme positions have, of course, been subjected to critique. Booij (2002: 32), for example, provided evidence against Anderson's A-morphous framework, namely that internal structure of derived words must remain visible in order for pluralization to apply correctly in Dutch. Borer (1998: 163) pointed out, on the other hand, that Lieber's attempt to reduce morphology to syntax succeeds only at the expense of making changes to X-bar theory that are not independently necessary for syntax; in other words, morphological principles insidiously creep back in, even in the most militantly antimorphological treatments.

Lying somewhere between the syntactic and antisyntactic poles is Distributed Morphology (Halle and Marantz, 1993). In this framework, word structure is hierarchical and morphosyntactic features are supplied in the syntax but the phonological forms of morphemes are inserted late in a derivation (after syntax) and may not be isomorphic with the morphosyntactic structure.

In spite of problems, syntactic treatments of various aspects of inflection and word formation have persisted and even proliferated since the early 1990s. Ackema (1995), for example, pursued the idea that morphology is a separate component of the grammar but that syntactic principles nevertheless apply within it. Thus, movement rules and binding principles are active below the word level, from which Ackema attempted to explain the properties of the passive and perfect constructions in Germanic and of auxiliary selection in Dutch.

Figure 2 Noun incorporation. (A) is a potential noun incorporation in Mohawk but (B) is not (Baker, 1988).

Syntactic treatments of morphology have also given rise to analyses of more exotic forms of word formation. Baker (1988) used the principles of Government-Binding theory to derive the properties of noun incorporation in languages such as Mohawk. For example, that Figure 2A is a potential noun incorporation in Mohawk but Figure 2B is not follows from the fact that Head Movement, a species of the general rule Move Alpha, is subject to the Empty Category Principle, which requires that a trace of movement be properly governed. Hale and Keyser (2002) proposed an incorporation analysis of English conversion verbs such as *saddle* and *shelve*. Rice (2000: 28) argued convincingly that the complex properties of templatic morphology in the Athapaskan family of languages could be made to follow from a syntactic account in which the verb has a complex hierarchical structure (see Figure 3).

Syntactic approaches to word formation continue to evolve, just as syntactic theory does. Recent Minimalist developments have begun to filter into the analysis of inflection and word formation. For example, in DiSciullo (2002) morphology and syntax are not isomorphic; nevertheless, they share the structural properties of dominance and precedence, as well as the basic relation of asymmetry that underlies such relations as c-command, 'complement of,' and 'specifier of.' Julien (2002), on the other hand, argued that morphology and sentential syntax should not be distinguished. In her analysis of tense and aspect marking, bound morphemes occur freely as heads in syntactic structures, and morphology is subject to such Minimalist-inspired principles as obligatory binary-branching and leftward movement. The payoff, she suggested, is that it becomes possible to predict correlations that seem to exist cross-linguistically between the form of tense-aspect marking (prefixing or suffixing) and basic clausal word order.

It is interesting that, even in these most recent developments, the tension persists between those theorists who wish to separate morphology from syntax, even while borrowing principles from syntax, and those who wish to merge the two completely.

Figure 3 The complex hierarchical structure of verbs in the Athapaskan languages (Rice, 2000: 28).

Syntax: Optimality Theory

D Wunderlich, Heinrich Heine University, Düsseldorf, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Some Basic Issues

Optimality Theory (OT) was originally developed for dealing with phonological problems, abandoning the assumption that grammatical constraints are inviolable (Prince and Smolensky, 1993, 2004; McCarthy and Prince, 1995). The fundamental new ideas were then soon adopted in other grammatical domains, too, in syntax (Grimshaw, 1997; Ackema and Neeleman, 1998; Grimshaw and Samek-Lodovici, 1998; Barbosa *et al*., 1998; Dekkers *et al*., 2000; Legendre *et al*., 2001) as well as in morphology (Legendre, 2000; Wunderlich, 2001).

The main innovations of OT can be summarized as follows:

1. Grammatical constraints can conflict with each other and are violable under certain conditions (not inviolable, as assumed before).
2. Grammatical constraints are ordered according to their respective weight (not equally ranked).
3. Different rankings of constraints are responsible for differences between individual grammars or languages. (What was formerly conceived as grammatical parameters is now reconstructed as constraints being differently ranked.)
4. A construction is grammatical (not only by virtue of its own properties, or by virtue of its generative history, but rather) if it wins the competition in a candidate set, because it satisfies best the higher-ranked constraints.

At first sight, many phenomena that had troubled linguists over years seemed to be good candidates for application of OT, such as variation in word order, selective blockings, morphological gaps, repairs, or the emergence of unmarked forms. However, as soon as one starts to analyze these phenomena more systematically, many important theoretical questions have to be answered. Must all the constraints belong to a universal set of constraints, or can there be language- or even construction-specific constraints, which are based on the instantiation of lexical categorization? Is it possible to represent cumulative constraints in situations where the effects of individual constraints seem to be added up? Which restrictions over constraints are necessary? Given the concept that each reranking of constraints defines a possible grammar, how can one avoid the problem of overgeneration of grammars? And how complex does the OT architecture develop, if one assumes an infinite set of candidates, each with its own internal structure? Is it possible to restrict the set of possible candidates, that is, to define some relevant set of candidates? How is optionality to be dealt with (where more than one candidate seems to be optimal), and how is

Syntax-Phonology Interface

S Inkelas, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Numerous phonological patterns have syntactically conditioned environments. In Italian, the gemination rule known as Raddoppiamento Sintattico applies to the second of two adjacent words only under certain specific syntactic conditions. For example, it applies between a verb and an adverb (1a) and between a noun and an adjective (1b), but it does not apply between a complex noun phrase and following adjective (1c) or between a noun and following complex adjective phrase (1d) (Nespor and Vogel, 1986):

(1a) parlo b:ene
'he spoke well'

(1b) devi comprare delle [mappe [di [citta v:ecchie]NP]PP]NP
'you must buy some maps of old cities'

(1c) devi comprare delle [mappe [di citta]PP vecchie]NP
'you must buy some old maps of cities'

(1d) devi comprare delle [mappe [di citta [molto vecchie]AP]PP]NP
'you must buy some maps of very old cities'

Numerous different aspects of syntactic structure have been found necessary to the description of phonological patterns, including syntactic bar level (e.g., Selkirk, 1982), heads vs. nonheads (Nespor and Vogel, 1986), and syntactic sisterhood or other configurational properties such as constituent command (c-command) (Kaisse, 1985). What is equally significant is that other aspects of syntactic structure have not been found to play any role; syntactic category (e.g., noun vs. verb), for example, or morphosyntactic features such as finiteness or tense appear in and of themselves never to be accessed by phonology.

The Characterization of Rule Domains

Since the pioneering work of Selkirk (1982), the dominant approach to syntactically conditioned phonology has been through the mediation of prosodic structure. Syntactic structures are the basis for generating phonological phrase structure, although configurationally they can be very different in any given case. Phonological patterns make reference solely to prosodic structure.

As initially proposed by Selkirk and developed further by Nespor and Vogel (1986) and Hayes (1989), prosodic structure (p-structure) is composed of the specific hierarchy of prosodic constituents in (2) (it is often assumed – see, e.g., Nespor and Vogel, 1986) – that the hierarchy of prosodic units extends below the word level to include the metrical constituents of foot and syllable. However, in light of many differences between metrical units and those that function as rule domains, a number of researchers have suggested that the two constituent types belong to separate hierarchies (Selkirk, 1986; Zec, 1988; Inkelas, 1990); for present purposes we may safely ignore the lower end of the prosodic hierarchy because only the constituents at and above the word level bear any relation to syntactic structure):

(2) phonological word
phonological phrase
intonational phrase
utterance

Each phonological rule applies within a selected prosodic domain.

As an illustration, the noun phrase from (1b) is reproduced with prosodic structure represented below:

(3)

The rule of raddoppiamento sintattico applies within the phonological phrase.

The prediction of approaching syntactically conditioned phonology through prosodic structure is that no matter how many syntactically conditioned phonological processes a language has, all will apply in one of the four domain types available to the language. Thus far, not many languages have been studied that have a large set of phrasal phonological alternations. This is an area in which rich descriptive work on individual languages is sorely needed.

The Impact of Surface Syntactic Structure on P-Structure

Although research into phrasal phonology is in some ways still in its infancy, the available data suggest two

major sources of syntactic influence on p-structure: end-based mappings, in which the beginnings or ends of major syntactic constituents define phonological phrase boundaries, and configuration-based mappings, in which words in a sentence are assigned to phonological phrases on the basis of their syntactic configurational relationships to one another.

End-Based Mappings

End-based mappings (Chen, 1987) impose phonological phrase junctures at the designated edge (either left or right) of syntactic constituents of a selected bar level, e.g., X" (XP). This approach has lent itself naturally to Optimality Theory, in which alignment constraints are responsible for the syntax-phonology mapping. An end-based mapping that targets the left edge of a maximal projection creates a phonological phrase break not only between each pair of consecutive maximal projections but also between a head and following XP complement, in a head-initial language. Italian fits into this language type, as shown in (2); so does Chi Mwi:ni (Swahili), as analyzed by Selkirk (1986), for example. In a head-final language, the same setting would cause complements and heads to phrase together, as documented for Korean by Cho (1990). The mirror-image situation occurs when it is the right edge of maximal projections that induces phonological phrase boundaries.

The expectation in an end-based mapping would be that phonological phrases will have a strict syntactic definition at one end but will be syntactically loose, i.e., quite variable in definition, at the opposite end. Scenarios of exactly this kind are documented in Shanghai by Selkirk and Shen (1990).

Configuration-Based Mappings

Configurational mapping algorithms are sensitive to relationships like sisterhood, c-command, and branchingness, i.e., properties of the hierarchical structure of a sentence rather than simply the locations where the edges of the constituents occur.

Evidence supporting configurational algorithms comes from languages in which branching syntactic constituents phrase differently from nonbranching ones. In English, for example, the Rhythm Rule, which retracts the first of two clashing primary stresses, operates within phonological phrases (Nespor and Vogel, 1986). It applies between a verb and adverb, for example, as in (4a), but not between a verb and a following complex adverbial phrase (4b):

(4a) rabbits [réproduce quìckly]$_{\phi}$
(4b) rabbits [rèprodúce]$_{\phi}$ [quíckly and prolifically]$_{\phi}$

Similar effects have been observed for verbs and branching vs. nonbranching objects and for adjectives and following noun phrases. The differential phrasing of branching vs. nonbranching syntactic constituents of comparable bar levels follows from a bottom-up mapping with a minimal size constraint on phonological phrases, as proposed in Zec and Inkelas (1990) or, nonderivationally, via a violable constraint requiring each syntactic constituent of a given bar level – e.g., XP – to correspond to a phonological phrase, with additional constraints guaranteeing that phonological phrases will not exceed or fall below a given size (see, for example, Truckenbrodt, 1999).

The expectation in a configuration-based mapping is that phonological phrases should basically be coextensive with syntactic constituents, *modulo* interference from recursive syntactic structure. Configuration-based algorithms have difficulty phrasing together words that are not syntactic sisters (as is easily accomplished in end-based algorithms) and need embellishment in such cases. However, end-based mappings based on a single edge – left or right – have difficulty in capturing the effect of syntactic branchingness and constituency on phonological phrasing.

Function vs. Content Words

Virtually all work on the syntax-phonology interface has recognized the difference between function and content words. Only the latter – prototypically nouns, verbs, adjectives, adverbs – universally acquire the status of phonological words (see, for example, Nespor and Vogel, 1986). Function words are often prosodically dependent, obligatorily joining in the same prosodic constituent – word or phrase – as an adjacent content word. This can have ramifications for stress or accent, which function words often lack, even in languages in which all content words must be accented; it can also have ramifications for phonological phrasing. Klavans (1985) documented a number of cases in which function words phrase differently than a content word in the same syntactic position would; function words can famously be prosodified with words of the syntactic constituent that they head, as is the case with the reduced auxiliary *is* in English: [*Ellen's*]$_{\phi}$ [*arriving tonight*]$_{\phi}$, where under no syntactic analysis does *is* bear a closer syntactic relationship to the subject than to the verb phrase.

The function/content word asymmetry also affects the computation of branchingness. In English, Hausa,

and Serbo-Croatian, for example, phonological phrase formation has been shown to be sensitive, not directly to the syntactic complexity of a syntactic constituent, but rather to the number of phonological words it contains. An example is Serbo-Croatian topicalization, which is subject to the constraint that the topic must be a branching phonological phrase (Zec and Inkelas, 1990). Topics consisting of only one phonological word are judged ungrammatical, as in (5b).

(5a) [[taj]ω [čovek]ω]NP voleo = je Mariju
that man loved = AUX Mary
'that man loved Mary'

(5b) *[[Petar]ω]NP voleo = je Mariju
Peter loved-AUX Mary
'Peter loved Mary'

'Heavy NP shift' in English is another well-known example of this kind.

Phonological Effects on Syntax

Syntax-phonology mapping is often thought of as unidirectional; indeed, many researchers assume, with Pullum and Zwicky (1988), that syntax is phonology free. However, a growing body of evidence suggests that phonology can also influence syntax, in the sense that particular syntactic configurations are allowed only if they would be phonologically well formed. The best-known examples are those in which phonological considerations influence word order, as in Serbo-Croatian topicalization. Other evidence for phonological constraints on syntax comes from the placement of second position clitics, notorious for having to follow the first word in some syntactic domain (see, for example, Zec and Inkelas, 1990; Halpern, 1992). In many cases it turns out that what clitics must follow is not the first syntactic terminal element in that domain but the first phonological word. This is illustrated for Serbo-Croatian by (6a) and (6b), which both mean 'that man presented her with it' and show that in Serbo-Croatian, second position clitics may follow either the first syntactic constituent ('that man') or the first syntactic word ('that'):

(6a) taj čkovek=***joj=ga=je*** poklonio
that man=*her=it=aux* presented

(6b) taj=***joj=ga=je*** čkovek poklonio
that=*her=it=aux* man presented

If, however, the first syntactic element happens not to be a phonological word, as is the case with the proclitic initial preposition in (7), second position clitics must follow not that element but the next. Sentences (7a), (7b), and (7c) all mean 'the piano is in this room.' In (7a), as in (6a), the clitic follows the first syntactic phrase. In (7b), the clitic follows the first syntactic element, resulting in ungrammaticality; in (7c), the clitic follows the first phonological word.

(7a) u = ovoj = ***je*** sobi klavir
in = this = *is* room piano

(7b) *u = ***je*** ovoj sobi klavir
in = *is* this room piano

(7c) u = ovoj sobi = ***je*** klavir
in = this room = *is* piano

The contrast between (7b) and (7c) shows that the syntactic positioning of clitics is sensitive to phonological word structure.

Directions of Future Research

Future work on the phonology-syntax interface will be illuminated by investigation of language types that have thus far been understudied in this respect, especially nonconfigurational languages. The growing interest by semanticists in focus and intonation will also surely inform the phonology-syntax connection in important ways.

Syntax–Pragmatics Interface: Overview

K Fukushima, Kansai Gaidai University, Hirakata, Japan

© 2006 Elsevier Ltd. All rights reserved.

Conflicting Priorities

Since the inception of generative grammar, formally oriented researchers have been aware of the significance of pragmatic factors for adequately describing/theorizing about the domain of syntax. Morgan (1975) and Gazdar (1980), for example, pointed to the inescapable pragmatic influence on sentence structure. This dependency of syntax on pragmatics, however, had largely been ignored by generative syntacticians for quite some time because they had been preoccupied by their quest for universal grammar. In contrast to this, functionally oriented thinkers considered communicative demands to be the primary motivation for grammar. Reflecting this state of affairs, there have been two general, major approaches to the syntax–pragmatics interface. The first is syntactico-centrism, which relegates pragmatics to the status of a secondary linguistic system, excluded from the self-contained syntactic component (or grammar in general). The second approach is pragmatico-centrism, which relegates syntax to derivative role and makes pragmatics central. However, a third approach, the syntax–pragmatics alliance, in which different degrees or depths of interaction between syntax and pragmatics are accommodated, has resurfaced recently, in particular from within the generative orientation.

Interface in Retrospect

The Centrality of Syntax

Proponents of syntactico-centrism are Gazdar and Klein (1977), Chomsky (1986), and Carston (1998). These researchers were agnostic about the exact nature of the interaction between syntax and pragmatics (especially the actual mechanisms involved) and treated pragmatics as a postgrammatical filter. Gazdar and Klein allocated a placeholder in the syntactic structure, to be filled with an extragrammatical pragmatic condition to determine the acceptability of the structure. Chomsky (1986) included pragmatics (use of language) as one agendum of linguistic inquiry, but considered the elucidation of language structure (knowledge of language) and its acquisition as having the priority status. Carston designated pragmatics as supplying a selection criterion for a particular sentential structure from a set of sentences with equivalent truth conditions (for example, *A dog bit you*/*You were bitten by a dog*/*It was a dog that bit you*). The criterion is based on the amount of 'processing effort' in the sense of the Relevance Theory (Sperber and Wilson, 1986; *see* **Relevance Theory**).

The Centrality of Pragmatics

Pragmatico-centrism is represented by Givón (1979) and Hopper (1987). Givón considered that loose, paratactic pragmatic discourse structures (the pragmatic mode) gave rise to tight, grammaticalized syntactic structures (the syntactic mode). The differences between the two are illustrated by the following (nonexhaustive) opposing characteristics: (1) topic-comment versus subject-predicate structure, (2) loose conjunction versus tight subordination, (3) slow versus fast rate of delivery, (4) word-order-based on old/new information versus case functions, and (5) absence versus elaborate use of grammatical morphemes. The opposing pairs are mirrored by the disparities observed between pidgins versus creoles, child versus adult language, and informal versus formal speech (*see* **Morphology in Pidgins and Creoles**; **Language Development: Overview**). To the extent that the first members of these pairs are considered to be 'prior,' the primacy of the pragmatic mode is justified. Even more radical is Hopper, who claimed that grammar is 'emergent' in the sense that discourse gives rise to and shapes structure (or regularity) as an ongoing

Syntax: Optimality Theory

D Wunderlich, Heinrich Heine University, Düsseldorf, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Some Basic Issues

Optimality Theory (OT) was originally developed for dealing with phonological problems, abandoning the assumption that grammatical constraints are inviolable (Prince and Smolensky, 1993, 2004; McCarthy and Prince, 1995). The fundamental new ideas were then soon adopted in other grammatical domains, too, in syntax (Grimshaw, 1997; Ackema and Neeleman, 1998; Grimshaw and Samek-Lodovici, 1998; Barbosa *et al*., 1998; Dekkers *et al*., 2000; Legendre *et al*., 2001) as well as in morphology (Legendre, 2000; Wunderlich, 2001).

The main innovations of OT can be summarized as follows:

1. Grammatical constraints can conflict with each other and are violable under certain conditions (not inviolable, as assumed before).
2. Grammatical constraints are ordered according to their respective weight (not equally ranked).
3. Different rankings of constraints are responsible for differences between individual grammars or languages. (What was formerly conceived as grammatical parameters is now reconstructed as constraints being differently ranked.)
4. A construction is grammatical (not only by virtue of its own properties, or by virtue of its generative history, but rather) if it wins the competition in a candidate set, because it satisfies best the higher-ranked constraints.

At first sight, many phenomena that had troubled linguists over years seemed to be good candidates for application of OT, such as variation in word order, selective blockings, morphological gaps, repairs, or the emergence of unmarked forms. However, as soon as one starts to analyze these phenomena more systematically, many important theoretical questions have to be answered. Must all the constraints belong to a universal set of constraints, or can there be language- or even construction-specific constraints, which are based on the instantiation of lexical categorization? Is it possible to represent cumulative constraints in situations where the effects of individual constraints seem to be added up? Which restrictions over constraints are necessary? Given the concept that each reranking of constraints defines a possible grammar, how can one avoid the problem of overgeneration of grammars? And how complex does the OT architecture develop, if one assumes an infinite set of candidates, each with its own internal structure? Is it possible to restrict the set of possible candidates, that is, to define some relevant set of candidates? How is optionality to be dealt with (where more than one candidate seems to be optimal), and how is

ineffability to be dealt with (where no candidate seems to be optimal)? Can OT also cover the phenomenon of gradient grammaticality? And last but not least, how can an OT grammar be learned? (This last issue is dealt with in Tesar and Smolensky, 2000.)

Many of these questions have been addressed in the phonological OT literature (Kager, 1999; McCarthy, 2004), as well as in the OT syntax. Lack of space prevents me from addressing these questions in detail. Moreover, note that OT syntax can be performed in the shape of several distinct morphosyntactic theories, such as Government and Binding theory (GB) or Minimalist Program (MP) (Grimshaw, 1997; Barbosa *et al.*, 1998; Müller, 2000; Legendre *et al.*, 2001), Lexical Functional Grammar (LFG; Bresnan, 2000, 2001), Lexical Decomposition Grammar (LDG; Wunderlich, 1999; Stiebels, 2000), or Role and Reference Grammar (RRG; Nakamura, 1999).

If one steps from phonological to morphological and finally to syntactic optimization, an important problem arises concerning the question of serial or parallel optimization. Under the parallel view, which is prevailing among researchers, even a rather complex construction is evaluated in one step, the different subaspects performed simultaneously, whereas under the serial view, several local optimizations (of the word, or of the clause) are performed cyclically. Kiparsky (2000) argues for the cyclic model as most realistic for the semitic verb morphology (distinguishing optimal stem and optimal word), see also Blevins (1997) and McCarthy (2000). On the basis of detailed analyses of various phenomena (including remnant movement, superiority, reflexives and binding, pied piping), Müller and co-workers argue for local, i.e., cyclic, optimization in the syntax (Heck and Müller, 2000; Müller, 2002; Fischer, 2004).

The candidate set is generated on the basis of a given input (underlying form). In the classic OT (the so-called correspondence theory), each candidate (a potential output) is evaluated according to faithfulness: dependence constraints penalize the occurrence of elements (or features) in the output that do not have a correspondent in the input, maximality constraints penalize the presence of elements (or features) in the input that do not have a correspondent in the output, and identity constraints penalize a featural mismatch between input and output. Needless to say, further constraints are needed to check the linear ordering in the output, whether some morpheme or constituent is initial or final, or whether it is immediately to the left or to the right of the verbal root/the finite verb, and so on. Grimshaw (1997) holds that the input for a syntactic evaluation must be some representation of meaning, for instance an LF representation; the same should hold for morphological evaluations. However, Heck *et al.* (2002), in discussing several examples of dependent as well as movement structures, come to the conclusion that input can be dispensed with in OT syntax. They argue that syntax is information-preserving, while phonology is not. This conclusion, however, crucially depends on a specific conception of syntax; it does not hold for LFG or LDG.

In the remainder of this article, more illustrative OT examples are given that concern syntactic movement, the constitution of optimal words, the selection of optimal case, the effects of harmonic alignment, and the selection of optimal agreement. The last section considers some further developments.

Syntactic Movements and Repairs

The pioneering work in OT syntax is Grimshaw (1997, manuscript 1994), dealing with the sentence structure of English (including interrogatives, *wh*-movement, *do*-support and negative-induced inversion) within GB. Observe that only the last of the sentences in (1) is grammatical.

(1a) *They will read what?
(1b) *Will they read what?
(1c) *What they will read?
(1d) What will they read?

The set of candidates based on the input 'read(they, which books)' includes structural representations of all potential strings constituted by the given items. Among the constraints Grimshaw assumes are the following:

(2) STAY: Do not move.
OP-SPEC: Operators are realized in SPEC position.
OBL-HD: Heads must be lexically filled.

The evaluation in Table 1 shows that two movements (in violation of STAY) are needed in order to satisfy the higher-ranked constraints. (The constraint columns are ordered from left to right; '*' indicates a violation, while '*!' indicates a fatal violation. The optimal candidate is indicated by '☞'.)

The same set of constraints explains the negative-induced inversion in (3) (Grimshaw, 1997: 401).

Table 1 Interrogatives in English (Grimshaw, 1997: 378)

Candidates	*OP-SPEC*	*OBL-HD*	*STAY*
a. [$_{IP}$ they will [$_{VP}$ read what]]	*!		
b. [$_{CP}$ will$_k$ [$_{IP}$ they t_k [$_{VP}$ read what]]]	*!		*
c. [$_{CP}$ what$_i$ [$_{IP}$ they will [$_{VP}$ read t_i]]]		*!	*
☞ d. [$_{CP}$ what$_i$ will$_k$ [$_{IP}$ they t_k [$_{VP}$ read t_i]]]			**

(3a) *She said that she would work this hard under no circumstances again.
(3b) She said that under no circumstances would she work this hard again.

Besides movement, many kinds of repairs have been investigated in OT syntax. They involve the introduction of empty elements such as expletives or *do* in English *do*-support. Another example of repair is the German *ersatzinfinitive*, which is the neutralized form of a past participle governing an infinitive (4b). This construction does not appear with durative verbs such as *bleiben* 'remain' (4c).

(4) German *ersatzinfinitive*
(4a) *Ich habe das Buch lesen gewollt.
I have the book read.INF want.PASTP
(4b) Ich habe das Buch lesen wollen.
I have the book read.INF want.INF
'I wanted to read the book.'
(4c) Die Leute sind stehen geblieben.
the people are stand.INF remain.PASTP
'The people remained standing.'

The solution proposed by Schmid (2002) makes use of the constraints in (5).

(5a) MORPH: morphological selectional properties of lexical items must be observed.
(5b) *PASTP/+INF.MOD: the past participle of a modal verb must not be a sister of a VP whose head is an infinitive.
(5c) *PASTP/+INF.DUR: the past participle of a durative verb must not be a sister of a VP whose head is an infinitive.

The avoid constraint is split into a family of constraints according to hierarchically ordered subclasses of verbs governing an infinitive; some are ranked higher than MORPH, while others are ranked lower. This is a standard solution for category-specific syntactic regularities (Table 2).

Lots of other syntactic problems have been discussed in the OT framework: long extraction, topicalization and focusing, word ordering in the German middle field, pied piping, quantifier scope, anaphoric binding, and resumptive pronouns.

Table 2 German *ersatzinfinitive* (Schmid, 2002: 145)

Candidates	**PASTP/ + INF.MOD*	*MORPH*	**PASTP/ + INF.DUR*
a. [[$_{VP}$ ... lesen$_{INF}$] gewollt$_{PASTP}$]	*!		
☞ b. [[$_{VP}$ ... lesen$_{INF}$] wollen$_{INF}$]		*	
☞ a. [[$_{VP}$ stehen$_{INF}$] geblieben$_{PASTP}$]			*
b. [[$_{VP}$ stehen$_{INF}$] bleiben$_{INF}$]		*!	

Optimal Words

An inflected word is constituted by various inflectional affixes attached to a stem. One point in question is how the ordering of affixes can be described best: is it possible to predict the ordering of affixes on the basis of a syntactic structure (according to the mirror hypothesis proposed by Baker), or are there language-specific templates that integrate all the idiosyncratic properties of individual languages? Many languages show patterns deviating from syntactic predictions, but on the other hand, the templatic account misses generalizations that one would like to make. The proponents of Minimalist Morphology (Wunderlich and Fabri, 1995) claim that inflectional affixes are (bound) lexical items that can be freely attached to a stem, thus yielding elements of a candidate set, which are evaluated by means of a constraint ranking.

Yimas, a language of Papua New Guinea, is a good case for illustration because it shows some variation as to how pronominal affixes are realized on the verb (Foley, 1991; Wunderlich, 2001). Besides free pronouns (always unmarked for case), Yimas exhibits ergative (E), accusative (A), and nominative (N) prefixes in the 1st and 2nd person, as well as ergative and nominative prefixes and dative (D) suffixes in the 3rd person. With transitive verbs, only E or A affixes show up, the former in case of 3rd person objects (6a), and the latter in case of 1st or 2nd person objects (6b); the marked case is always closer to the stem. However, in the combination 1Ag/2Pat one finds either a pronominal gap with the free variant of the pronoun instead (6c), or a repair phenomenon, namely a fused morpheme (6d).

(6) Transitive verbs in Yimas
(6a) Ergative pattern:
na- mpu- tay pu- ka- tay
3sgN- 3plE- saw 3plN- 1sgE- saw
'They saw him.' 'I saw them.'
(6b) Accusative pattern:
pu- ŋa- tay ma- ŋa- tay
3plN- 1sgA- saw 2sgN- 1sgA- saw
'They saw me.' 'You saw me.'
(6c) Gap in the combination 1Ag/2Pat:
ipa kul-tay (*ipa-kul-tay, *ipwa-kay-tay)
1pl 2plA-saw 1plN-2plA-saw 2plN-1plE-saw
'We saw you(pl)'
(6d) Fused morpheme in the combination 1Ag/2sgPat:
ipa kampan-tay (*ipa-nan-tay,
1pl 1E/2sgA-saw 1plN-2sgA-saw
*ma-kay-tay)
2sgN-1plE-saw
'We saw you(sg)'

With ditransitive verbs, the dative is only possible in case of 3rd person recipients (7a); otherwise the recipient is marked accusative, so that ergative and accusative can be combined (7b). In the combination of 1st and 2nd person (Ag or Rec), one finds either a gap (7c) or the same fused morpheme as above (7d). (VI represents the gender class.)

(7) Ditransitive verbs in Yimas
(7a) Ergative pattern plus D:
uraŋ k- ka- tkam-r- mpun
coconut.VIsg VIsg- 1sgE- show-PERF-3plD
'I showed them the coconut'
(7b) Three-partite pattern N-E-A:
uraŋ k- mpu- ŋa- tkam-t
coconut.VIsg VIsg- 3plE- 1sgA- show-PERF
'They showed me the coconut'
(7c) Gap:
ipa uraŋ k- kul- tkam-t
1pl coconut.VIsg VIsg- 2plA- show-PERF
(*k- nan- ŋa- tkam-t)
VIsg-2plE-1sgA- show-PERF
'We showed you(pl) the coconut'
(7d) Fused morpheme:
uraŋ k- mpan- tkam-t
coconut.VIsg VIsg- 1E/2sgA- show-PERF
(*k- ka- nan- tkam-t)
VIsg-1sgE-2sgA-show-PERF
'I showed you(sg) the coconut'

In the context of a modal prefix, nominative turns to ergative, as shown in (8).

(8) Modal prefixes in Yimas
(8a) ama-tmuk-t
1sgN-fall-PERF
'I fell down'
(8b) ant-ka-tmuk-t
POT-1sgE-fall-PERF
'I almost fell down.'
(8c) pu-ŋa-tpul
3plN-1sgA-hit
'They hit me.'
(8d) ka-mpu-ŋa-tput-n
LIKE-3plE-1sgA-hit-PRES
'They are going to hit me.'

The constraints that can deal with the observed distribution include the following:

(9) Morphological constraints in Yimas (slightly simplified). ('M' indicates the morphological or word domain.)
(9a) MAX(arg)$_M$: all arguments are realized by pronominal affixes.
(9b) *(arg)$_M$/+FOCUS: avoid pronominal affixes for arguments that bear the feature [+FOCUS]
(9c) PERSON: the higher person is realized closer to the stem (scale: $1 > 2 > 3$).
(9d) DEFAULT: every linking domain displays the default linker (nominative).
(9e) NOM-INITIAL: nominative prefixes only appear word-initially.
(9f) CASE: the less marked case is realized closer to the stem (scale: ACC > ERG).
(9g) IDENT(person): all person features have identical values in the input and the output.

Most of these constraints follow from universal conditions. It is better to realize an argument pronominally than nominally, and it should be realized in the closest possible domain (which is the word in Yimas) (9a). However, an argument that introduces a new referent in the discourse, or is questioned or relativized (all three situations could be described by the feature [+FOCUS]), should not be realized by a pronominal affix, because pronouns generally are less suitable to bear focus (9b). *(arg)$_M$/+FOCUS thus automatically restricts MAX(arg)$_M$. The person scale $1 > 2 > 3$ (or $1, 2 > 3$) is universal, but how it interacts with ordering problems is free (9c). (In Maung, a language of Australia, it is the lower person that is realized closer to the stem Donohue, 1998.) All case systems include nominative as the default case (9d). The nominative prefixes of Yimas are nearly identical to the free pronouns and probably originate from cliticization; this explains why (9e) holds (called EDGEMOST in Legendre, 2000). The markedness scale ACC > ERG is universal, but again, the way it interacts with ordering problems is free (9f). Finally, IDENT (person) is also universal.

The requirements of PERSON and CASE conflict with each other in case of the 1Ag/2Th (or 1Ag/2Rec) combination, and here the position of IDENT(person) in the constraint-ranking is decisive. In Yimas, a gap is more easily tolerated than neutralization of person (while in Dalabon, a language of Australia, neutralization is preferred: a 1st person object can be realized by a 3rd person prefix Evans *et al.*, 2001). However, which of the two arguments then becomes gapped in the morphology is still open. Only if one adds the ranking MAX (ACC) » MAX(ERG) ('Realize ACC/ERG') does one obtain the desired result, as shown in Table 3. We will turn to these constraints in the next section.

Conflicting alignment constraints leading to gaps (or repairs) have also been considered by Legendre (2000) and Gerlach (2002), who studied the formation of clitic sequences in South Slavic and Romance, respectively.

Optimal Case

Syntactic clauses are usually headed by a verb, which can have several arguments: one (intransitives), two (transitives), three (ditransitives), or even four or five (causativized ditransitives, and so on). One major issue is therefore the set of conditions that regulate case, realized by pronominal affixes or by morphological case; one may also regard syntactic positions of arguments as a realization of 'abstract case.' Most accounts consider the semantic roles of arguments as the determining factor. However, a purely structural account is possible under the assumption that the arguments of a predicate are strictly ordered

Table 3 A gap introduced by conflicting ordering constraints: evaluation in the combination 1Ag/2plRec (or 1Ag/2plTh without the first 3N-prefix)

Candidates	*PERSON*	*CASE*	*ID(PERSON)*	*MAX(arg)$_M$*	*MAX(ACC)*	MAX(ERG)
3N-1E-2A	*!					
3N-2A-1E		*!				
3N-3E-2A			*!			
3N-1E				*	*!	
☞ 3N-2A				*		*

(normally, of course, controlled by some semantic conditions, but often also idiosyncratically). In many instances (such as causativization), the argument hierarchy can be read off from the decomposition of the complex predicate. Lexical Decomposition Grammar (LDG, Wunderlich, 1997; Wunderlich and Lakämper, 2001; Stiebels, 2002) assumes that this hierarchy inheres abstract case, which is then realized by morphological or syntactic means.

The argument roles of a hierarchy can be encoded by means of two relational abstract case features: [+hr] 'there is a higher role,' and [+lr] 'there is a lower role' (similar to an earlier proposal by Kiparsky). The highest argument is [−hr] ('there is no higher role'), and the lowest argument is [−lr] ('there is no lower role'); in addition, depending on the presence of further arguments, the positive features are encoded. Thus, canonical encoding yields the following theta-roles (lambda abstractors over arguments):

(10) Abstract case features:
(10a) intransitives: λx verb(x)
[−hr,−lr]
(10b) transitives: λz λx verb(x,z)
[+hr,−lr] [−hr,+lr]
(10c) ditransitives: λz λy λx verb(x,y,z)
[+hr,−lr] [+hr,+lr] [−hr,+lr]

However, single features can be overridden by specific lexical assignments, which often reflect semantic conditions. For instance, dative-subject verbs such as German *gefallen* or Icelandic *likar* (both 'like') can be characterized by (11) and thus suggest the experiencer-reading 'The highest argument behaves as affected.'

(11) Lexical assignment in the presence of abstract case:
λz λx verb(x,z)
[+hr,−lr] [+**hr**,+lr]

The same features (but only those with positive values) are used to characterize overt case:

(12) DAT: [+hr,+lr]
ACC: [+hr]
ERG: [+lr]
NOM: [ ]$_{case}$

Observe that dative is only compatible with the medial argument of ditransitive verbs or the lexically marked argument in (11), while accusative is compatible with more arguments (including all those that could in principle be realized by dative). Finally, nominative as the maximally underspecified case is compatible with all arguments. Therefore, further constraints are necessary; this approach to case thus calls for OT. In this framework, lexical items with the format of (10) or (11) constitute the input, and the relevant output candidates have to show some pattern of overt case.

The relation between input and output is minimally determined by faithfulness (MAX); in addition, markedness controls that not too many features are realized.

(13a) MAX(+F): Every feature [+F] in the input has a correspondent in the output.
(13b) *[+F]: Avoid [+F] in the output.

The rankings MAX(+hr) $\pi \gg$ *[+hr] and *[+lr] π MAX (+lr) characterize a pure accusative system, while the reverse rankings characterize a pure ergative system. However, dative can appear in both types of system, which has to be guaranteed by a further constraint (MAX(+hr,+lr)), which ranks above both MAX(+hr) and MAX(+lr). Moreover, lexically assigned features should have precedence (14a) (see also Woolford, 2001), nominative should appear for reasons of economy (14b), and the morphological cases of a local domain should be distinct (14c).

(14) General case constraints
(14a) MAX(lexF): every lexically assigned feature in the input has a correspondent in the output.
(14b) DEFAULT: every linking domain displays the default linker (nominative).
(14c) UNIQUENESS: each linker applies only once in a local domain.
(14d) MAX(+hr,+lr): every feature combination [+hr,+lr] in the input has a correspondent in the output.

Wunderlich (2003) shows that this inventory is also sufficient to characterize all case patterns occurring in

Table 4 Lexically marked distransitive verbs

	z	y	x	MAX (lexF)	DEFAULT	UNIQUENESS	MAX (+hr, +lr)	MAX (+hr)	*[+lr]	MAX (+lr)	*[+hr]
☞	DAT	ACC	NOM				*		*	**	**
	ACC	DAT	NOM	*!			*		*	**	**
	DAT	DAT	NOM			*!			**	*	**
	ACC	ACC	NOM	*!		*	**			***	**

Table 5 Passive of lexically marked ditransitive verbs

	z	y	MAX (lexF)	DEFAULT	UNIQUENESS	MAX (+hr, +lr)	MAX (+hr)	*[+lr]	MAX (+lr)	*[+hr]
☞	DAT	NOM				*	*	*	*	*
	NOM	DAT	*!			*	*	*	*	*
	DAT	ACC		*!		*		*	*	**
	DAT	DAT		*	*			**		**

German and Icelandic, provided that all noncanonical case patterns are characterized by additional lexical features. Moreover, these two languages share the same constraint-ranking (although Icelandic exhibits by far more marked case patterns). How this constraint-ranking works is illustrated here for lexically marked ditransitive verbs and their passives (Tables 4, 5).

(15) Lexically marked ditransitive verbs:

(15a) weil der Arzt den Patienten
because the.NOM doctor the.ACC patient
einem Test unterzog
a.DAT test exposed
'because the doctor exposed the patient to a test'

λz	λy	λx	EXPOSE(x,y,z)
lexical	**+lr**		
default	+hr	+hr	−hr
	+lr	+lr	

(15b) weil der Patient einem Test
because the.NOM patient a.DAT test
unterzogen wurde
exposed was
'because the patient was exposed to a test'

λz	λy	∃x	EXPOSE(x,y,z)
lexical	**+lr**		
default	+hr	+hr	
	+lr		

Stiebels (2000, 2002) bases her typology of linking systems on the inventory given in (13) and (14). Further OT work on optimal case includes Nakamura (1997, 1999) in RRG and Woolford (2001) in GB.

Harmonic Alignment

Harmonic alignment is an OT concept that captures implicational generalizations (Prince and Smolensky, 1993). Suppose a scale X > Y, next to a scale a > b > . . . > z. Then harmonic alignment of the two dimensions is the pair of the following scales:

(16a) X/a ⊃ X/b ⊃ . . . ⊃ X/z
(16b) Y/z ⊃ . . . ⊃ Y/b ⊃ Y/a

A possible interpretation is that X and Y are linguistic entities, where X is more frequent or more expressive or less marked than Y. The elements of the other scale are possible contexts, ordered according to salience. Then X/a ('X in the context of a') is less marked than X/b, whereas Y/a is more marked than Y/b. What is more marked is likely to be more avoided. Therefore, the constraint alignment is a pair of constraint hierarchies:

(17a) *X/z ≫ . . . ≫ *X/b ≫ *X/a
(17b) *Y/a ≫ *Y/b ≫ . . . ≫ *Y/z

Aissen (1999) was the first who applied this concept to morphosyntactic phenomena. She assumed subject > object as the first scale, and the animacy or definiteness scale as the contextual scale. Silverstein (1976) observed that ergative is often restricted to 3rd person as opposed to 1st or 2nd person, to inanimates as opposed to humans, or to indefinites as opposed to definites, thus characterizing various kinds of ergative split. A similar, but reversed split is found with objects: accusative is often restricted to 1st or 2nd person, to animates or to definites; this is analyzed in OT by Aissen (2003).

Aissen's account is rather complicated, and it fails to give a conceptually and empirically satisfying solution. The main reason is that she appeals to grammatical roles (subject, object) rather than case features. Stiebels (2000, 2002) proposes to make use of the scale [+hr] > [+lr] instead: "It is better to mark a lower argument (an object) than a higher argument (the subject)." Given the salience scales 1, 2 > 3, animate > inanimate, definite >indefinite, pronoun > noun, imperfect > perfect, harmonic alignment then yields the constraint hierarchies in (18) without further complications. (For convenience, +hr is abbreviated as ACC, and +lr is abbreviated as ERG.)

(18a)	*ERG/1,2	≫ *ERG/3	*ACC/3	≫ *ACC/1,2
(18b)	*ERG/ +ANIM	≫ *ERG/ −ANIM	*ACC/ −ANIM	≫ *ACC/ +ANIM
(18c)	*ERG/ +def	≫ *ERG/ −def	*ACC/ −def	≫ *ACC/ +def
(18d)	*ERG/ +pro	≫ *ERG/ −pro	*ACC/ −pro	≫ *ACC/ +pro
(18e)	*ERG/ −perf	≫ *ERG/ +perf	*ACC/ +perf	≫ *ACC/ −perf

Effects that are based on these universal tendencies are found in the inventory of pronouns or pronominal affixes ('emergence of the unmarked'), as well as in all sorts of case splits. Yimas (see 'Optimal Words') has accusative affixes in the 1st and 2nd person, but lacks them in the 3rd person (according to *ACC/3 ≫ *ACC/1,2). A similar case is Dyirbal, a Pama-Nyungan language of Australia (Dixon, 1994): pronouns of the 1st and 2nd person can only be marked for accusative (*-na*), while demonstratives as well as nouns can only be marked for ergative (*-ŋgu*). Such a language allows for four different case patterns with transitive verbs: ERG-ACC, ERG-NOM, NOM-ACC, and NOM-NOM; each is signaling a certain salience distribution of subjects and objects.

Hindi also displays these four case patterns: ergative is restricted to perfect, whereas accusative is only found with human, specific animate or definite inanimate objects.

(19) The four-way case-split of Hindi (Mohanan, 1994)

(19a) niinaa-ne baalikaa-ko uthaa-y-aa.
Nina.F-ERG girl-ACC lift-PERF-M
'Nina lifted up a/the girl.'

(19b) niinaa baalikaa-ko uthaa-eg-ii.
Nina.F.NOM girl-ACC lift-FUT-F
'Nina will lift up a/the girl.'

(19c) niinaa-ne roTii khaa-y-ii.
Nina.F-ERG bread.F.NOM eat-PERF-F
'Nina ate bread.'

(19d) niinaa kelaa khaa-eg-ii.
Nina.F.NOM banana.M.NOM eat-FUT-F
'Nina will eat a banana.'

A split can also occur between two coexisting case-linking devices. Warlpiri, another Pama-Nyungan language of Australia, shows ergative case on nouns and pronouns, but accusative-based agreement: *-rna* '1sg' agrees with the subject of both intransitive and transitive verbs (20a, 20b), while *-ju* '1sg' agrees with the object (20c); consequently, *-ju* has to be classified as accusative (A), and *-rna* as nominative (N).

(20) Ergative case and accusative agreement in Warlpiri (Andrews, 1985: 106f.)

(20a) Ngaju ka-rna parnka-mi.
1.NOM PRES-1sg.N run-NONPAST
'I am running.'

(20b) Ngajulu-rlu ka-rna-ngku nyuntu nya-nyi.
1-ERG PRES-1sg.N-2sg.A you.NOM see-NONPAST
'I see you.'

(20c) Ngaju ka-npa-ju nyuntulu-rlu nya-nyi.
1.NOM PRES-2sg.N-1sg.A you-ERG see-NONPAST
'You see me.'

Such a mixed system in which head-marking exhibits the accusative type and case-marking the ergative type is found in several languages, whereas the reverse constellation does not exist. This fact again follows from harmonic alignment, if we consider the agreement morpheme as a bound pronoun ($pron_M$): the two scales ACC > ERG and $pron_M$ > pron ('Morphological realization is preferred') induce the constraint hierarchies *ACC/pron ≫ *ACC/$pron_M$ and *ERG/$pron_M$ ≫ *ERG/pron, so that a split with ACC only on pronouns and ERG only on affixes is ruled out.

Zeevat and Jäger (2002) propose a functional explanation of the effects of harmonic alignment. They argue that the contextualized constraints, such as those in (18), emerge from statistical generalizations about the perceived linguistic input rather than being part of grammar. However, an unequal distribution of ACC and ERG in the data must have been produced by speakers prior to learners' perception. The assumption of a cognitive rationale of the scales to be combined therefore seems more plausible.

Optimal Agreement

Grammatical agreement is a phenomenon in which word forms that co-occur in a clause exhibit covariation. Inflected forms often agree with respect to their

values of number, gender, or person, as can be seen from the contrasting examples in (21). All items in (21a) refer to a single (feminine) entity, whereas in (21b) they refer to a plural (masculine) entity.

(21) French
(21a) La^{fsg} fille^{fsg} est^{3sg} belle^{fsg}.
'The girl is beautiful.'
(21b) Les^{pl} garçons^{mpl} sont^{3pl} beaux^{mpl}.
'The boys are handsome.'

Languages that use rich agreement often allow more freedom in word order, as can be seen from the following example from Latin.

(22) Grandia per multos tenuantur flumina rivos.
(Ov. *Rem*. 445)
big.npl to numerous.mpl.ACC dissolve.3pl
river.npl stream.mpl.ACC
'Big rivers dissolve into numerous streams'

However, the extent to which agreement is observed differs from language to language. Besides languages that show multiple agreement, there are also languages that avoid agreement under specific conditions or in certain domains, as well as languages that lack agreement altogether.

Some languages exhibit an agreement split with respect to number, similar to the various types of case splits discussed in the preceding section. Georgian shows plural agreement only with animate subjects (23b), whereas Classical Arabic does not allow plural agreement for nonpronominal postverbal subjects, where instead the neutralized singular form is found.

(23) Georgian (Harris, 1981: 21)
(23a) Burt-eb-i gorav-s/ *gorav-en.
ball-pl-NOM roll-3sg/ roll-3pl
'The balls are rolling.'
(23b) Knut-eb-i *gorav-s/ gorav-en.
kitten-pl-NOM roll-3sg/ roll-3pl
'The kittens are rolling.'
(24) Classical Arabic (Aoun *et al*., 1994: 197, 205)
(24a) Naam-a /*naam-uu l-ʔawlaad-u.
slept-3sg.m / slept-3pl.m DEF-children-NOM
'The children slept.'
(24b) *Naam-a /naam-uu hum.
slept-3sg.m / slept-3pl.m PRON.pl.m
'They slept.'

Ortmann (2002) provides an OT analysis of these phenomena. He assumes the expressivity scale +pl > [ ] ('Plural is more informative than underspecification') and the two salience scales animate > inanimate, pronoun > noun. Harmonic alignment yields the two markedness scales in (25).

(25a) *(+pl)/inan ≫ *(+pl)/anim
(25b) *(+pl)/noun ≫ *(+pl)/pron

The interpretation of these avoid constraints is that it is more marked to realize plural for referents of low salience than for those of high salience. Interpolating these constraint hierarchies with the relevant MAX constraint (MAX(+pl)$_{S\text{-}AGR}$: 'Realize plural in the subject agreement') yields the possible rankings in (26).

(26a) MAX(+pl)$_{S\text{-}AGR}$ ≫ *(+pl)$_{S\text{-}AGR}$/inan ≫ *(+pl)$_{S\text{-}AGR}$/anim
(unrestricted agreement: German)
(26b) *(+pl)$_{S\text{-}AGR}$/inan ≫ MAX(+pl)$_{S\text{-}AGR}$ ≫ *(+pl)$_{S\text{-}AGR}$/anim
(restricted agreement: Georgian)
(26c) *(+pl)$_{S\text{-}AGR}$/inan ≫ *(+pl)$_{S\text{-}AGR}$/anim ≫ MAX(+pl)$_{S\text{-}AGR}$
(no agreement: Chinese)

Languages thus differ with respect to different cut-off points regarding the various possible salience scales, and, of course, they can also make different choices with respect to subject agreement, object agreement, and possessor agreement.

Ortmann (2000, 2002) also deals with another phenomenon. Hungarian (unlike English or German) avoids NP-internal plural agreement. Attributive adjectives do not agree with the noun (27a), and in the context of a numeral, which inherently contains the concept of plurality, the noun must not be marked for plural (27b). However, demonstratives (outside of DP) agree with the noun (27c).

(27) Hungarian plural agreement (Ortmann, 2000, 2002)
(27a) gyors hajó-k
fast ship-pl
'fast ships'
(27b) öt hajó
five ship.sg
'five ships'
(27c) Ez-ek a hajó-k gyors-ak.
this-pl DEF ship-pl fast-pl
'These ships are fast.'
(27d) Az öt hajó gyors.
DEF five ship.sg fast.sg
'The five ships are fast.'
(27e) Az öt nagynéni sör-t isz-ik
DEF five aunt.sg beer-ACC drink-3sg
/ *isz-nak.
/ *drink-3pl
'The five aunts drink beer'

Moreover, subject agreement strictly respects the value of number instantiated on the head element of the subject DP or DemP (27c–27e). This latter fact

Table 6 Evaluation of Hungarian antiagreement with pronominal possessor

	*(+pl)$_{P\text{-}AGR}$/noun	MAX(+pl)$_{P\text{-}AGR}$	*MULT-PLUR	MAX(+pl)	*(+pl)$_{P\text{-}AGR}$/pron
PRON.3sg house-P.3sg		*!		**	
☞ PRON.3sg house-P.3pl				*	*
PRON.3pl house-P.3sg		*!		*	
PRON.3pl house-P.3pl			*!		*

Table 7 Evaluation of Hungarian antiagreement with nominal possessor

	*(+pl)$_{P\text{-}AGR}$/noun	MAX(+pl)$_{P\text{-}AGR}$	*MULT-PLUR	MAX(+pl)	*(+pl)$_{P\text{-}AGR}$/pron
aunt.3sg house-P.3sg		*		**!	
aunt.3sg house-P.3pl	*!			*	
☞ aunt.3pl house-P.3sg		*		*	
aunt.3pl house-P.3pl	*!		*		

suggests cyclic optimization: first, the DP is checked (with the nominal head being singular in (27d, 27e) despite the cardinality > 1, and the resulting information is taken as input for subject agreement.

Ortmann proposes the constraint *MULTIPLE-PLUR(DP) (DP-referents receive only one realization of 'plurality' within the DP), which penalizes any uneconomic plural assignment in the DP. This constraint also interacts with a plurality split in the Hungarian possessor agreement, which results in so-called antiagreement; actually, the DP-internal possessor never agrees with the agreement information on the head noun, as shown in (28).

(28) Hungarian possessor antiagreement (Ortmann, 2002: 170)

(28a) az ö ház-uk
DEF PRON.3sg house-POSS.3pl
'their house'

(28b) a nagynéni-k ház-a
DEF aunt-pl house-POSS.3sg
'the aunts' house'

In harmony with the salience split (of Classical Arabic) as discussed above, it is better for the head noun to agree with a pronoun than with a full noun, and because of *MULTIPLE-PLUR(DP) dominating MAX(+pl), only one plural marking should appear in the DP. (MAX(+pl) summarizes the requirements for morphological and syntactic realization.) Table 6 and Table 7 illustrate how the effects of antiagreement come about by the constraint ranking.

The morphology and syntax of agreement is certainly one of the aspects in which languages differ widely, this topic thus being one of the most interesting parts of linguistic typology.

Further Developments

In contrast to classic OT, Stochastic OT (Boersma, 1998; Boersma and Hayes, 2001) constraints are ranked on a continuous scale: every constraint is assigned a real number, which determines the ranking between them and is a measure for the distance between them. For each evaluation, the placement of a constraint is modified by adding a noise with normal distribution, so that the actual placement of the constraints after adding this noise value can vary if the constraints are close to each other. However, if the constraints are more distant, a categorical ranking results. This account can incorporate linguistic variation that was outside the scope of classic OT. Bresnan *et al.* (2001) study the role of person in active–passive variation. In Lummi (Straits Salish, British Columbia), for example, the person of the subject argument cannot be lower than the person of a nonsubject argument (the star in Table 8 represents ungrammaticality). The same constraints that result in a categorical effect in Lummi are then shown to give rise to statistical preferences in English, which are modeled in stochastic OT.

Besides OT syntax, also OT semantics has been developed, which is concerned, among others things, with the interpretation of pronouns (Hendriks and de Hoop, 2001). Integrating the two perspectives (speaker-oriented: what is an optimal form? and hearer-oriented: what is an optimal interpretation?), Blutner (2001) proposed Bidirectional OT, which has been formalized by Jäger (2002, 2004). All candidates are <form, meaning> pairs, and the optimal candidate wins the competition of independent variation of both meaning and form. (In the weak version

Table 8 Active–passive variation in Lummi and English

	Lummi		*English*	
	active	*passive*	*active*	*passive*
1,2 subject, 3 object	obligatory	*	frequent	rare
3 subject, 1,2 object	*	obligatory	rare	frequent

of bidirectional OT, the evaluation is recursive.) This account offers an adequate solution of blocking phenomena, such as **more cheap* in the presence of *cheaper*, and it singles out <*cause to die*, cause death in indirect way> vs. <*kill*, cause death in direct way> as optimal pairs. Lee (2001) explains the 'emergence of the unmarked' effect on word order in scrambling languages (free word order freezes into a fixed, canonical order under certain circumstances) using bidirectional optimization. Bidirectional OT is promising in various domains because it allows for a unified account of optionality and ineffability on the one hand, which are problematic for production OT, and of ambiguity and uninterpretability on the other hand, which are problematic for comprehension OT (Beaver and Lee, 2004).

Syntax–Pragmatics Interface: Overview

K Fukushima, Kansai Gaidai University, Hirakata, Japan

Conflicting Priorities

Since the inception of generative grammar, formally oriented researchers have been aware of the significance of pragmatic factors for adequately describing/theorizing about the domain of syntax. Morgan (1975) and Gazdar (1980), for example, pointed to the inescapable pragmatic influence on sentence structure. This dependency of syntax on pragmatics, however, had largely been ignored by generative syntacticians for quite some time because they had been preoccupied by their quest for universal grammar. In contrast to this, functionally oriented thinkers considered communicative demands to be the primary motivation for grammar. Reflecting this state of affairs, there have been two general, major approaches to the syntax–pragmatics interface. The first is syntactico-centrism, which relegates pragmatics to the status of a secondary linguistic system, excluded from the self-contained syntactic component (or grammar in general). The second approach is pragmatico-centrism, which relegates syntax to derivative role and makes pragmatics central. However, a third approach, the syntax–pragmatics alliance, in which different degrees or depths of interaction between syntax and pragmatics are accommodated, has resurfaced recently, in particular from within the generative orientation.

Interface in Retrospect

The Centrality of Syntax

Proponents of syntactico-centrism are Gazdar and Klein (1977), Chomsky (1986), and Carston (1998). These researchers were agnostic about the exact nature of the interaction between syntax and pragmatics (especially the actual mechanisms involved) and treated pragmatics as a postgrammatical filter. Gazdar and Klein allocated a placeholder in the syntactic structure, to be filled with an extragrammatical pragmatic condition to determine the acceptability of the structure. Chomsky (1986) included pragmatics (use of language) as one agendum of linguistic inquiry, but considered the elucidation of language structure (knowledge of language) and its acquisition as having the priority status. Carston designated pragmatics as supplying a selection criterion for a particular sentential structure from a set of sentences with equivalent truth conditions (for example, *A dog bit you*/*You were bitten by a dog*/*It was a dog that bit you*). The criterion is based on the amount of 'processing effort' in the sense of the Relevance Theory (Sperber and Wilson, 1986; *see* **Relevance Theory**).

The Centrality of Pragmatics

Pragmatico-centrism is represented by Givón (1979) and Hopper (1987). Givón considered that loose, paratactic pragmatic discourse structures (the pragmatic mode) gave rise to tight, grammaticalized syntactic structures (the syntactic mode). The differences between the two are illustrated by the following (nonexhaustive) opposing characteristics: (1) topic-comment versus subject-predicate structure, (2) loose conjunction versus tight subordination, (3) slow versus fast rate of delivery, (4) word-order-based on old/new information versus case functions, and (5) absence versus elaborate use of grammatical morphemes. The opposing pairs are mirrored by the disparities observed between pidgins versus creoles, child versus adult language, and informal versus formal speech (*see* **Morphology in Pidgins and Creoles**; **Language Development: Overview**). To the extent that the first members of these pairs are considered to be 'prior,' the primacy of the pragmatic mode is justified. Even more radical is Hopper, who claimed that grammar is 'emergent' in the sense that discourse gives rise to and shapes structure (or regularity) as an ongoing

Figure 1 Ross's performative hypothesis: In a declarative sentence, there is an extra layer of syntactic projection with a phonetically empty speech act verb taking a null subject (speaker) and object (addressee).

Figure 2 The neoperformative hypothesis: A declarative sentence structure is projected by the speech act head (sa, speech act; sa*, 'lower shell' structure of the SaP. SaP, speech act projection). Adapted from Speas and Tenny (2003).

process. An emergent structure is neither determined nor fixed – it is constantly open and in flux. In this view, grammar is simply a name given to certain categories of observed repetitions in discourse.

Classical Attempts at Syntax–Pragmatics Integration

Classical variants of the syntax-pragmatics alliance are the proposals by Ross (1970) and Gordon and Lakoff (1971). Ross suggested that on top of a declarative sentence, there is an extra layer of syntactic projection with a phonetically empty speech act verb taking a null subject (speaker) and object (addressee), as shown in Figure 1. His performative hypothesis was an attempt to represent pragmatic aspects as syntactic constituents. However, as is well known, Ross's approach fails to distinguish the following two sentences in terms of truth conditions: *John laughed* (a contingent fact) and *I claim that John laughed* (true when uttered). With the recent development of more elaborate syntactic apparatuses, Ross's idea has been reincarnated, as described in the next section.

Gordon and Lakoff (1971), who employed conversational postulates as a component for a transderivational rule. To derive (1) *why paint your house purple?* from (2) *why do you paint your house purple?*, the conversational postulate 'Unless you have some good reason for doing *x*, you should not do *x*' is supposed to be entailed by the logical structure of (2), a class of contexts, and a set of conversational postulates. Their approach was an attempt to constrain syntactic derivation pragmatically. According to Green (2004), Gordon and Lakoff confused a speaker's intentions and beliefs with semantic matters of truth. Although it is true that the contextual use-interpretation relation associated with a linguistic form is dependent on the speaker's and addressee's beliefs and intentions about one another's beliefs and intentions, Gordon and Lakoff's approach obscured this aspect.

Pulling All That Together

Syntactico-centrists do not at all deny the relevance of pragmatics for syntax; the interaction between syntax and pragmatics is simply not a central concern for them. But why not? (See Newmeyer, 1998). Also, as suggested by Givón (1995), pragmatico-centrists need to take syntactic structure seriously. After all, some items of the pragmatic mode are made available courtesy of **syntactic** mechanisms assembling constituents in accordance with some ordering or combinatory criteria. Because syntax and pragmatics interact with, influence, and complement one another, it would be desirable if we could devise ways to synthesize the two. Recent attempts at achieving such a goal are illustrated in the next section.

Interface Now: The Syntax–Pragmatics Alliance Revisited

Functional Categories and Pragmatics

With the advent of functional categories in the Chomskyan Principles and Parameters framework (e.g., Agr and D heads projecting AgrP and DP) (*see* **Principles and Parameters Framework of Generative Grammar; Generative Grammar**), a path was cleared for the inclusion of abstract syntactic elements in a structural description. Researchers investigating languages with topic-focus structures quickly embraced the creation of pragmatically oriented functional

categories (such as Focus Phrase), which opened up possibilities for describing languages, such as Hungarian, that had evaded a rigid English-centered theoretical mold (e.g., Hörvath, 1985; Kiss, 1995; see also Szendröi, 2004).

The invention of pragmatically oriented functional heads (as seen, e.g., by Cinque, 1999) soon came to include **syntactic** projections for speech act (**sa**), evaluativity (**eval**), and evidentiality (**evid**) (Speas and Tenny, 2003). As an example embodying such a neoperformative hypothesis, compare Figure 2, which represents a declarative sentence structure projected by the **sa** head. The pragmatic roles, Speaker (the 'agent' of a speech act), Utterance Content (the 'theme'), and Hearer (the 'goal'), are not primitives but defined structurally: Speaker c-commands state of knowledge within utterance content, making Speaker the locus of the point of view. From the declarative structure, a syntactic transformation derives an interrogative structure, as shown in Figure 3. Hearer is now the closest c-commander for state of knowledge and the point of view is attributed to Hearer. Imperative and subjunctive **sa** structures are shown in Figures 4 and 5 respectively.

Figure 3 A syntactic transformation deriving an interrogative structure from the declarative structure.

The motivation for such speech act projections (SaPs) is the fact that languages, out of many possible illocutionary acts, grammaticalize only up to five or six distinct types. More significantly, there appear to be agreement-like phenomena involving Speaker and Hearer, for example, the Arabic complementizer '*inna* and the morpheme *nuwa* in Mupun (Mwaghavul), respectively.

What is peculiar about SaPs is the lack of correspondence between actual speech acts and the particular, syntactically defined speech act structures. Thus, the Utterance Content of any syntactic type (*modulo* the choice of tense) can, in principle, be embedded under a given SaP, and its speech act property is determined by the SaP's configurational characteristics. Because, for example, Speas and Tenny recognized the multifunctionality (claim, promise, request, etc.) of the declarative SaP, they needed but lacked an additional interpretive mechanism to determine the **actual** speech act type of the SaP.

Let us consider the following direct/rhetorical question: *Who can defeat Godzilla?* Embedding this within either the interrogative or declarative SaP structure seems to superficially guarantee the desired interpretations. Why, then, can the imperative sentence, *(you) beware of Godzilla!*, not be subjunctive (since both are [-finite])? The difference between the two seems to hinge on their pragmatically determined conventional use. This means that, to obtain proper embedding of Utterance Content within an SaP structure, the speech act type of Utterance Content needs to be determined **prior to** such embedding. That seems to render the pragmatic relevance of SaP structures questionable. Speas and Tenny appeared to be

Figure 4 A syntactic structure for an imperative sentence.

Figure 5 A syntactic structure for a subjunctive sentence.

preoccupied with a narrow range of pragmatico-syntactic phenomena (e.g., agreement, point of view, etc.); also, they seemed to be hampered by their **exclusive** reliance on syntactic concepts, from which pragmatic notions are **unidirectionally** obtained as derivatives.

An Inclusive Theory of Grammar and Pragmatics

Another way to implement the syntax-pragmatics alliance is by employing what Fukushima (2002) called an "inclusive theory of grammar," such as a framework like Head-Driven Phrase Structure Grammar (HPSG) (see Pollard and Sag, 1994; Sag *et al.*, 2003; *see* **Head-Driven Phrase Structure Grammar**). Here, grammar is a collection of linguistic constraints on lexical and nonlexical linguistic signs (words and phrases), expressed via feature structures (with FEATURE-value pairs). The linguistic constraints are **both** grammatical (phonology, category, **and** content) and pragmatic (context). An example of such a set of constraints or properties is the lexical sign *John* in Figure 6. The sign *John* satisfies the following constraints: It is a noun (syntax), used to refer to a third-person singular referent (semantics), who bears the name *John* (pragmatics). (The shared structures are indicated in Figure 6 by [1], showing the identity of feature values.) In such a feature structure, linguistic constraints are imposed on linguistic signs **simultaneously** and **nondirectionally**. No privilege, for example, is given to syntactic over pragmatic information.

Let us see how such a framework can be called on to handle speech acts. The illocutionary force of warning, for example, is rendered as in Figure 7. It says that a linguistic sign with the phonological shape [1] can be uttered by a speaker [2] to an addressee [3]. This is done in order to bring about a state of affairs in which the speaker's uttering [1] to the addressee results in the addressee's becoming aware of a danger, originating from some unspecified element [4]. Thus, the same technical apparatus both is used as a grammatical description and serves to elucidate illocutionary conditions.

Figure 6 An inclusive theory of grammar: The lexical sign *John* as a set of constraints.

Figure 7 The illocutionary force of warning; SOA (state of affairs) is roughly equivalent to a proposition, and ref-intend is shorthand for the sequence of predicates *intend-recognize-intend-believe*. Adapted from Green (2000).

Figure 8 The lexical definition of *beware*. Adapted from Green (2000).

Based on this, we can account for the behavior of lexical items with restricted syntactic distribution, such as the verb *beware*: *Beware of Godzilla!* and *I want you to beware of Godzilla* but not **I'm confident I'll beware of Godzilla*. As part of its lexical definition, *beware* makes reference to the pragmatic condition on warning in Figure 7, as indicated in Figure 8. The lexical definition tells us that *beware* is a verb that is used uninflected and takes two arguments, $NP_{[3]}$ and $PP_{[5]}$. The subject [3] watches out for the object [5], and the speaker [2] believes that the object endangers the subject.

An extended version of HPSG simultaneously accommodates constructional (syntactic), clausality (semantic), and illocutionary (pragmatic) aspects of sentences (Ginzburg and Sag, 2000; Ginzburg *et al.*, 2003, the latter another instance of the neo-performative hypothesis) and allows us to solve our previous question-imperative dilemma. First, the *illocutionary-relation* type *ask-relation* is normally associated with a *clausality* type *question*. Given that there is no contextual infelicity, the direct question is simply a question. Second, the *illocutionary-relation* type *assert-relation* is normally associated with the *clausality* type *proposition*. One illocutionary condition (similar to Figure 7) that is associated with the direct question construction allows it to be a rhetorical question. With that, a conversational implicature (in BACKGROUND) – arising from the fact that uttering the direct question (*ask-relation*) in a given context is insincere – helps establish a new connection between the *illocutionary-relation* type *assert-relation* and the clausality type *question*, overriding the default association between *ask-relation* and *question* (*see* **Implicature; Mood, Clause Types, and Illocutionary Force**). In contrast, no illocutionary condition would allow the imperative construction (of the *clausality* type *outcome*) to be compatible with subjunctive use. This type of account is available due to the inclusiveness of the HPSG architecture, in which grammatical information and pragmatic information can be brought together and synthesized under a single structural representation.

Summary

A syntactic theory that claims to be a viable basis for explaining language use in real time cannot avoid the issue of the syntax–pragmatics interface. After some 30 years of neglect, attempts have now resumed to identify the proper ways of approaching the problems existing in this domain (although so far, no definitive conclusions have been reached). Such attempts need to consider (nonexhaustively) questions regarding (1) ways of representing pragmatic information in conjunction with a structural description; (2) ways of accommodating the psycholinguistic properties of language processing, in particular incrementalness and speed; and (3) the adequacy of the performative hypothesis (see Kühnlein *et al.*, 2003b).

Syntax–Semantics Interface

J-P Koenig, University at Buffalo, Buffalo, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

'Syntax' in this article refers to the organization of the words in a sentence and to the set of rules or constraints that organize words into sentences. 'Semantics' refers to the meaning of words and sentences and to the rules or constraints by which the meanings of sentences are built from the meanings of words. It is widely believed that the ability to combine words (and morphemes) to build more complex

meanings from these syntactic combinations is a hallmark of human languages. Modeling this ability is one of the central aims in linguistics. The study of this ability is the study of the interface between syntax and semantics, and answers to this question distinguish the major current theoretical frameworks.

The Model of Perfection: Artificial Languages

To understand the issues that have occupied researchers, it is useful to compare natural languages with artificial or formal languages: Whether or how natural languages differ essentially from artificial languages helps classify current views. Artificial or formal languages are typically explicitly designed to be 'perfect' in the following sense. For each way of combining two or more syntactic expressions, there corresponds a unique way of combining the meaning of the expressions that are syntactically combined. Technically, an isomorphism can be defined between the syntactic and semantic components of formal languages. As a result, the meaning of formulas of arbitrary complexity is easily and unambiguously read from their syntactic surface organization. The formal language used to express referring expressions in arithmetic provides a simple example of this 'perfection.' The following are the syntactic formation rules for addition and multiplication.

- Syntactic rule 1: Number names and number variables are syntactically well-formed expressions called terms.
- Syntactic rule 2: If a and b are syntactically well-formed expressions, so is $\ulcorner(a+b)\urcorner$.
- Syntactic rule 3: If a and b are syntactically well-formed expressions, so is $\ulcorner(a*b)\urcorner$.

To each of these syntactic rules there corresponds a well-defined semantic rule.

Figure 1 The parallel between (A) syntactic composition and (B) semantic composition in the language of arithmetic.

- Semantic rule 1: Terms refer to numbers.
- Semantic rule 2: A formula of the form $(a+b)$ refers to the sum of the referent of a and the referent of b.
- Semantic rule 3: A formula of the form $(a*b)$ refers to the product of the referent of a and the referent of b.

The one-to-one correspondence between the syntactic rules and the semantic rules unambiguously indicates which computations are needed to obtain the referent of an expression of any complexity. Arithmetic expressions wear the needed computations to derive their referents on their sleeves, so to speak. As the two trees in Figure 1 informally depict, we can establish a one-to-one correspondence between syntactic computations and semantic computations. Such correspondences are known as homomorphisms or isomorphisms between syntax and semantics, depending on whether two different syntactic rules may or may not have the same semantic import. Only homomorphisms are relevant for natural languages.

The hypothesis that the interface between natural languages' syntax and semantics works like that of formal languages goes back to the German mathematician Gottlob Frege (although it is not clear that Frege held that view; see Pelletier, 2001). Frege's principle, the principle of compositionality, is defined as:

> Principle 1. Compositionality Principle (Frege's principle): The meaning of an expression is a function of the meaning of its parts and the way the parts are combined.

More operationally, since Montague (1974), the principle is understood to mean that we can establish a one-to-one correspondence or homomorphism between syntactic and semantic operations (see Janssen, 1997, for a good review). The models of the interface between the syntax and semantics of natural languages that have been proposed in the last 30 years can be profitably categorized on the basis of:

1. Whether they claim that natural languages differ **essentially** from the language of simple arithmetic formulas, that is, whether there is a homomorphism between the syntax and semantics of natural languages.
2. Whether the claimed correspondence (if any) must exist between syntactic **rules** and semantic **rules** (as Montague originally claimed) or between the syntactic and semantic **structures** that these rules output.

Where Natural Languages Seem Imperfect

Interfacing syntax and semantics would become a rather trivial task if natural languages' syntactic rules/constraints/structures paired with their semantic rules/constraints/structures as straightforwardly as in the case of the language of simple arithmetic. If natural languages are as 'perfect' as the language of simple arithmetic, they are not obviously so. Thus, claiming that there is no 'important theoretical difference' between formal and natural languages, as Montague (1974: 188) did, is a bold and noteworthy claim. Below are sentences that illustrate some of the mismatches (the 'imperfections') typical of natural languages. Discussions of how to appropriately model the interface between the syntax and semantics of these and similar classes of sentences has occupied much of the literature in the last 30 years.

(1a) It seems that John is tired.
(1b) John seems to be tired.

(2a) Who(m) did John see?
(2b) Jean a vu qui?
Jean has seen who(m)

(3a) Everyone loves someone.
(3b) $\exists x(\text{human}'(x) \wedge (\forall y(\text{human}'(y) \rightarrow \text{love}'(y, x))$
(3c) $\forall y(\text{human}'(y) \rightarrow \exists x(\text{human}'(x) \wedge (\text{love}'(y, x))$

(4a) Mary played.
(4b) Mary will play.

(5a) Mary began the beer.
(5b) Mary enjoyed the novel.

Sentence (1b) is an example of what is called (subject-to-subject) raising and, at least at a coarse level of analysis, is truth-conditionally equivalent to (1a). In both cases, the referent of *John* is the semantic argument of the meaning of the VP (*be*) *tired*; but only in sentence (1a) is *John* the subject of that VP. A consequence of this common semantics but distinct syntax is that the same combination of a subject and a VP does not seem to always have the same semantic import. In the case of the embedded clause of sentence (1a), that syntactic combination means the application of the VP meaning to the subject's meaning; in the case of *John* and *seems to be tired* in sentence (1b), it appears that it does not because the referent of *John* does not appear to be a semantic argument of the meaning of *seems to be believed*. In other words, more than one semantic function might correspond to the combination of an NP and a VP.

Figure 2 The difference between (A) English-style and (B) French-style questions.

The second example's relevance is slightly different. Let us assume that the meanings of questions expressed by sentences such as (2a) can be represented as in (6).

(6) for which animate x, John saw x

Then the surface structure of (2a) mirrors the semantic structure of (6). But the surface structure of the corresponding French sentence in (2b) (and other interrogative utterances in *in situ* languages) does not mirror its semantic structure (assuming that the semantics of English and French questions is the same). The difference is most easily seen in Figure 2. The syntactic position of *who* matches the semantic position of its translation in (6). Syntactically, *who* takes as its right sister a tree whose root is labeled S (its syntactic scope); semantically, the denotation of *who* is an operator that takes a propositional function as operand (its semantic scope). But *qui*, which is embedded within the verb phrase in French does not match its semantic scope (at least on the surface). No homomorphism seems to exist between syntactic and semantic structures for *in situ wh*-questions (although a homormorphism might still exist between syntactic and semantic rules).

Sentences such as (3a) have been at the center of many theories of the interface between the syntax and semantics of natural language. Such sentences are semantically ambiguous. According to one reading, there is at least one person that everybody loves, say *Gandhi*. Another reading is one in which, for each individual, there is at least one person he or she loves, but not all individuals need love the same entity; to each his or her own loved ones. The two first-order predicate logic formulas in (3b) and (3c) represent these two distinct readings. (*Everyone* and *someone* are understood here as equivalent to *every x that is human* and *some x that is human*; *human′*, *love′* and other′ expressions represent the meaning of the corresponding English words.) If we believe that these different readings correspond to different meanings of sentence (3a) (an assumption which may be challenged; see later discussion), sentences such as (3a) seem to contravene the claim that natural languages are 'perfect' because (3a) appears to have only one syntactic structure. We thus, have at least two semantic functions for combining a quantified direct

object with the verb: one in which the semantic output is such that the subject has wide scope over it and one in which the semantic output does not force the subject to have wide scope over it. Contrary to the homomorphism hypotheses, there does not seem to be a unique semantic rule for every grammatical combination (here, the combination of verbs and direct objects).

The sentences in (4) exemplify the same problem as the sentences in (2) but within a single language. Under the assumption that, semantically, tense operators take propositions or event descriptions as operands (see Dowty, 1979; de Swart, 1998), the morpho-syntactic structure of (4a) does not match its semantic structure (even leaving aside the occurrence of the subject outside the verb phrase). The morpho-syntactic expression of the tense operator is a suffix on a word (the verb *play*), whereas its semantic translation takes a full event description or proposition as argument – something typically expressed as a VP or clause – as informally shown in (7).

(7) TENSE [EVENT DESCRIPTION/ PROPOSITION]

Example (4b) shows that English is not only 'illogical,' it is not systematic, in that the same semantic function (tense operators) can be expressed as an independent word that takes a verb phrase as complement or as a suffix on the verb.

Finally, example (5) illustrates that what is literally expressed does not provide all the intuitive semantic content we ascribe to utterances. What Mary began in (5a) is *drinking the beer* and in (5b) *reading the book* (possibly *writing the book*). Semantic content seems to have to be interpolated between the semantic translation of the verb and the semantic translation of the direct object, a phenomenon dubbed 'coercion' in the computational semantics literature (Moens and Steedman, 1988; Pustejovsky, 1995).

Theories of the Syntax–Semantics Mismatch

Existing grammatical frameworks make different hypotheses about how the syntactic–semantic mismatches mentioned in the previous section can be resolved and about how artificial languages' perfection is reflected in natural languages. We can distinguish at least three general hypotheses; each is currently actively being explored.

- Hypothesis 1. Deep Split Structural Isomorphism (DSSI): Natural languages' imperfection is true of the surface syntactic structure of sentences. But strings can be assigned different structures at different levels of representation, and, for each kind of semantic relation, there is at least one level at which syntactic structures match very closely (if not entirely) the relevant aspects of semantic structures.
- Hypothesis 2. Natural Language Perfection (NLP): Natural languages' imperfection is only apparent. A single semantic combination rule can in fact be assigned to every combination of syntactic expressions (although the syntactic category of natural language expressions might then need to be flexibly assigned).
- Hypothesis 3. Imperfections Reflect the Architecture of Grammars (IRAG): Natural languages' imperfection is the result of their architecture (or even the architecture of the mind). Syntax and semantics are independent generative systems that are related through correspondence rules. Although there are regularities in how structures generated by one system are related to structures generated by the other, no homomorphic relation can be expected.

Proponents of these hypotheses typically focus on distinct subsets of the mismatches mentioned in the previous section. The DSSI hypothesis, for example, which goes back at least to the 1960s (see Lakoff, 1971), does not focus on coercion phenomena. The IRAG hypothesis, on the other hand, does not focus on quantifier scope mismatches. How easily each approach can tackle the **entire** set of mismatches or even whether they should (i.e., whether these mismatches form a natural class) is unclear at this point. This section focuses on the mismatches that each hypothesis models and, in particular, those mismatches whose analyses are easiest to present briefly.

The Deep Split Structural Isomorphism Hypothesis

The descriptive import of the DSSI hypothesis is most easily seen in typical analyses of examples (3a) and (4). Maintaining the DSSI hypothesis in the face of these surface mismatches leads to the claim that sentence (3a) has two distinct syntactic structures at the LF level of representation (often called

Figure 3 The s-structure representation of sentence (3a).

L(ogical)-F(orm)), but a single syntactic structure at another level (often called s-structure) (see May, 1985; see Chomsky, 1995, and subsequent work in the Minimalist Program for a slightly different, but conceptually similar, model of these phenomena). Technically, these distinct structural analyses are generated by using two sets of rules, a set of context-free rules (e.g., those in (8) for sentence (3a)) and one or more additional (transformational) rules such as that in (9). In (8), the notation NP[±Q] is used as a variable to range over all NPs, whereas NP[+Q] ranges over only NP quantifiers. In (9), t_i is a placeholder that indicates where the NP quantifiers moved from and is called a trace. (These rules are adapted from Chierchia and McConnell-Ginet, 2000.)

(8a) S → NP[±Q]VP
(8b) VP → V NP[±Q]|VP
(8c) NP[+Q] → Det N|everyone|someone
(8d) Det → every|a
(8e) N → man|woman
(8f) V → loves

(9) $[_S \ldots \text{NP}[+\text{Q}] \ldots] \Rightarrow [_S \text{NP}[+\text{Q}]_i [_S \ldots t_i \ldots]]$

The context-free rules in (9) generate the single s-structure-level syntactic tree in Figure 3. Subsequent applications of the transformational rule in (9) results in the two LF-level syntactic trees in Figures 4 and 5, depending on which of the NP[+Q] is targeted first. The two relevant readings of sentence (3a) now receive two distinct representations at one level of representation, and the homomorphism principle can be maintained if we assume the semantic interpretation of sentence (3a) is read from its LF representations. (Strictly speaking, homomorphisms require that 'operations' be defined in both domains put into correspondence, e.g., syntax and semantics. Thus, the output structures for which an homomorphism exists must be reanalyzed in terms of a local tree-building operation. Alternatively, the notion of order-homomorphism between structures outputed by the grammatical rules can be used, the relevant order being here tree-inclusion; see Cohn, 1981.) Compare the relative depth of embedding of the two quantified NPs in Figures 4 and 5 with that of the corresponding quantifiers in the first-order predicate logic formulas for the two readings of sentence (3a) in Figures 6 and 7.

The distinction in morpho-syntactic encoding that tense morphemes receive both within English and crosslinguistically is subject to a similar kind of analysis for proponents of the DSSI hypothesis. The homomorphism hypothesis can be maintained because a single surface expression can have two different structures at two distinct levels of representation. In particular, tense can have syntactic scope over the structure that denotes an event description (or proposition) at one level of representation (the d-structure, or its equivalent in the Minimalist Program) but not at another level of representation. The common structure of sentences (4a) and (4b) at the d-structure level is represented in Figure 8.

The distinct surface expression of the morpheme encoding tense in sentences (4a) and (4b) follows from operations similar to the transformational rule in (9) and the assumption that these operations are sensitive to the distinction between affixes such as *-ed* and free morphemes such as *will*. The contrast in the encoding of time in English is only the tip of the iceberg. Different tenses and various aspect markers may vary in their surface expression within a single language and across languages. The strategy just outlined can be applied generally to all these cases (see Cinque, 1999, for one of the most detailed explorations of this possibility).

Similar accounts are provided for the data set in (2). More generally, the claim that 'deep down' the interface between syntax and semantics is more transparent than what surface strings suggest requires

Figure 4 LF structure for the wide-scope existential reading of sentence (3a).

Figure 5 LF structure for the narrow-scope existential reading of sentence (3a).

Figure 6 A tree representation of the wide-scope existential reading of sentence (3a).

Figure 7 A tree representation of the narrow-scope existential reading of sentence (3a).

providing each surface string with several distinct syntactic analyses:

- An analysis that allows predicate–argument relations (including predicate–argument relations of tense, aspect, and modal operators) to be homomorphically read from the syntactic tree (e.g., an analysis that reads the tense predicate/VP argument relation from the syntactic structures of trees such as the one in Figure 8, i.e., from structures **before** verb stems move).
- An analysis that allows quantifiers and other scoping relations that do not involve a predicate-argument relation (focus vs. 'presupposed,' topic vs. comment, and so forth) to be homomorphically read from another syntactic tree (e.g., an analysis that reads the quantifier/scope relation from the syntactic structure of trees such as the ones in Figures 4 and 5 i.e., from structures that **result** from moving the NP quantifiers.)
- An analysis that represents the structure of the surface string.

To mediate among these analyses, successive applications of a general rule similar to (9) is posited. Morphemes, words, or phrases whose semantic interpretation contravenes their surface syntactic position must be moved to or from a position where the semantic interpretation of the local syntactic structure that they participate in can be easily read. For example, to account for the event description or propositional nature of the semantic argument of the past tense operator in sentence (4a), the past tense morpheme takes as syntactic complement at d-structure a structure that includes the verb stem for *play*, in conformity with its semantic constituency; subsequent movement of the verb stem ensures that it combines with the syntactically higher affix to form the surface verb form *played*. Similarly, the quantifiers *everyone* and/or *someone* in sentence (3a) are assumed to 'covertly' move to a position in which their semantic scope is easier to read from the local tree they are part of. As a result, the syntactic notion of hierarchical

Figure 8 The d-structure representation of sentences in (4).

superiority (or c-command) matches the semantic notion of wide scope (at least in the traditional first-order predicate calculus representation of scope dependencies). Note that, the mapping of syntactic tree configurations onto semantic configurations must precede the movement operation in the case of the movement of the verb stem, but must follow the movement operation in the case of the movement of quantifiers. (Alternatively, the syntax-to-semantics mapping targets the position of the moved constituent, or head of a chain in the sense of Chomsky, 1981, for quantifiers, but targets the position of the trace of the moved constituent for verb stems and raised NPs such as *John* in (1b).)

In theories that follow the just-outlined general model of the interface between syntax and semantics, one syntactic structure can be provided from which the relevant part of semantic representations can be homomorphically read. But, there is no **single** such structure, a state of affairs that is seen by some as effectively abandoning the spirit of Frege's compositionality principle (Jacobson, 2002). But, proponents of the DSSI hypothesis have stressed that the kind of structural operations and configurations necessary to model sentences such as (3a) or (4) are at play in syntactic processes that do not bear on the interface between syntax and semantics. Strictly syntactic constraints might thus provide independent evidence for the semantically more complex DSSI hypothesis (see May, 1985; Hornstein, 1995). Whether the adduced similarities between strictly syntactic constraints

Figure 9 Derivation of the semantic representation of the narrow-scope existential reading of sentence (3a).

and the operations/structures presented in this section are sufficient to weaken Frege's principle remains a subject of debate.

The Natural Language Perfection Hypothesis

Hypothesis 2 answers the interface challenge by denying that natural languages have any real imperfections or that natural languages relate their syntax and semantics in a qualitatively distinct manner from artificial languages. The impression of imperfection comes merely from too simple a view of the rules available to combine natural language expressions and the erroneous reification of the notion of syntactic constituent structure. The compositionality of natural languages, in this view, pertains to the pairing of a set of semantic and syntactic rules (the rule-to-rule hypothesis of Bach, 1976), not to a pairing of the structures that these rules output. In contrast to the DDSI hypothesis, the NLP hypothesis claims that the homomorphism between syntax and semantics need not be split into two partial homomorphisms (to infer from surface expressions predicate–argument relations and operator–scope relations). It also claims that the syntax–semantics correspondence is best understood in terms of syntactic and semantic rules rather than between syntactic and semantic structures (local tree configurations, *modulo* the previously mentioned caveats). The NLP hypothesis goes back at least to Montague's work. It has been adopted by several different theories (e.g., Klein and Sag, 1985; Steedman, 2000; Copestake *et al.*, 2001); it is the hallmark of the Categorial Grammar/Lambek Calculus tradition. Steedman (2000) provides one of the most articulate versions of this approach. In his analysis of example (3a), as is common to all approaches that assume that the translation from syntactic structure/categories to semantic structure/categories is local (the rule-to-rule hypothesis), each expression is assigned both a syntactic and semantic category, and each combinatorial rule affects both the syntactic and semantic categories of the expressions it combines. Syntactically, *loves* is taken to be a functor that must combine with a direct object NP to its right and a subject NP to its left to form a sentence. This syntactic subcategorization is written (S\NP)/NP. For illustrative purposes, quantified NPs such as *everyone* and *someone* are treated syntactically as either NPs or functors that must combine with a VP to their right to form a sentence or with a verb to their left to form a VP. This second syntactic subcategorization is written S/(S\NP) and (S\NP)\((S\NP)/NP), respectively. Semantically, *love* denotes a predicate missing two arguments, and *everyone* and *someone* denote predicates missing one argument each. Making use of λ-abstraction to model unsaturated argument positions, the meaning of *love* can be represented as:

$$\lambda y.\lambda x.\mathrm{love}'(x, y)$$

and that of *everyone* and *someone* as

$$\lambda p.\forall x(\mathrm{human}'(x) \rightarrow p(x))$$

and

$$\lambda q.\exists y(\mathrm{human}'(y) \wedge p(y))$$

respectively. Three principles of combination are relevant to modeling sentences (3a) (a few more universal principles, plus language-specific constraints on these principles, are the only other things that are needed to model the interface between the syntax and semantics of natural languages, according to this view):

- Function application, the combination of an argument/complement and a predicate/functor: Combining (in that order) x and $y\backslash x$ or y/x and x yields a y.
- Type-raising, making an argument/complement into a predicate/functor: An expression of category x can be assigned to the category $y/(y\backslash x)$ or $y\backslash(y/x)$.
- Function composition, composing two functors: Combining (in that order) two functors x/y and y/z yields x/z.

The derivations of the two relevant readings of sentence (3a) are given in Figures 9 and 10. (For ease of exposition, type-raising operations are assumed to have applied in the lexicon and are not represented.) The interpretation of sentence (3a) in which the existential quantifier has narrow scope over the

Everyone	loves		
$S/(S\backslash NP)$: $\lambda p.\forall x(human'(x) \rightarrow p(x))$	$(S\backslash NP)/NP$: $\lambda y\lambda x.(love'(x, y))$	*FC*	someone
S/NP : $\lambda y.\forall x(human'(x) \rightarrow (love'(x, y))$			NP $\lambda q.\exists y(human'(y) \wedge q(y))$
S: $\exists y(human'(y) \wedge (\forall x(human'(x) \rightarrow love'(x, y))))$			*FA*

Figure 10 Derivation of the semantic representation of the wide-scope existential reading of sentence (3a).

universal quantifier follows from two uses of function application (*FA* in Figure 9; standard steps that simplify the resulting semantic formulas are omitted). The interpretation of sentence (3a) in which the existential quantifier has wide scope over the universal quantifier follows from the use of function composition first and then the use of functional application (*FC* and *FA* in Figure 10).

The two possible derivations of sentence (3a) outlined in Figures 9 and 10 clearly obey Frege's principle and the rule-to-rule hypothesis. To each syntactic combination of two of its substrings corresponds a unique combination of the semantic representations of those two substrings. Leaving aside a few additional complexities, modeling the other mismatches previously mentioned, takes a similar form under this view. Alternative derivations (leading to either distinct surface expressions of the same semantic content or distinct semantic content for the same surface expressions) stem from the (at times nondeterministic) interaction of a handful of combinatory principles (function application, various forms of function composition, and type-raising). Proponents of the NLP hypothesis, thus, provide rule-based, truly compositional models of the interface between syntax and semantics. Whether operations posited by such models, like the operations/structures posited by DSSI models, have independent, purely syntactic justifications remains controversial.

The Imperfections Reflect the Architecture of Grammars Hypothesis

The IRAG hypothesis, which is more recent and less fleshed out than the previous two hypotheses, takes the interface challenge to reflect a deep truth about the architecture of natural languages (if not the mind). In this view, natural languages are 'imperfect' because each level of analysis (syntax and semantics) has its own 'agenda,' so to speak, and although these 'agendas' are typically aligned, they need not be. The analysis of the sentences in (5) given in Jackendoff (1997) (see also Sadock, 1991, for an early proposal) best illustrates this hypothesis. The context-free rules in (8) account for the (simplified) syntactic structure of sentence (5a), as shown in the tree in Figure 11.

Two sets of correspondence rules link the syntactic structure diagrammed in Figure 11 or that of the more explicit expression of its content in sentence (10a) and their common semantic representation. (*Begin* is assumed here to denote a two place predicate whose two arguments are an actor and a type of action; informally, BEGIN′(*x* actor, *y* action).)

(10a) Mary began drinking the beer
(10b) Mary began reading the book

The rules for interpreting the more explicit versions of sentences (5) in (10) are informally formulated as follows.

1. Interpret *begin* as BEGIN′.
2. Interpret the denotation of (definite) direct object NPs as semantic arguments of the denotation of verbs.
3. Interpret VP complements of verbs as denoting action arguments of the interpretation of verbs.

To model the 'nondefault' correspondence between the syntactic relation of the verb and its direct object and their semantic relation in sentences such as (5), Jackendoff posits rule 4 as an alternative to rule 2.

4. Interpret NP as *F(Int(NP))* (i.e., as the unspecified activity denoted by *F* and involving the interpretation of *NP*).

The application of rules such as rule 4 must be further constrained so as to not apply in the 'default' case (see Sadock, 1990, for suggestions and Jackendoff, 2002, for more details).

The IRAG hypothesis resembles the DSSI hypothesis in claiming that syntactic structures are linked to semantic structures (*modulo* the previously mentioned caveats) and that correspondence rules take the form: Configuration X in syntax corresponds to configuration Y in semantics. But it views the assumption that semantic structures can **always** be read from syntactic structures (as in the DSSI hypothesis)

Figure 11 The syntactic structure of sentence (5a).

Figure 12 LF structure for the narrow-scope existential reading of sentence (11).

or the syntactic formation rules that have applied (as in the NLP hypothesis) as an illusion created by the existence of default correspondence rules. The IRAG hypothesis also ressembles the NLP hypothesis in positing a direct pairing of syntactic and semantic types (NPs and F(Int(NP)) in rule 4, or the syntactic category and meaning of lexical items). But it insists that syntax and semantics are independent generative systems that derive their outputs on their own, and thus it views mismatches not as illusions but as evidence for this architectural independence or representational modularity (Jackendoff, 1997).

Shaking Things Up

How Specified Is Grammatical Meaning?

All the approaches discussed in the previous section presume that grammatical meaning (the output of interfacing the syntactic and the semantic components of a grammar) is a message whose content is similar to a logician's proposition (or its conceptual equivalent). The relevance of some of the examples in (2)–(5) to models of the interface between syntax and semantics depends on this presumption. Consider example (3a). The existence of one surface syntactic structure but two readings for this sentence is part of what motivates the DSSI hypothesis and the postulation of multiple syntactic levels of representations. Similarly, the two sequences of rules deriving the two readings of sentence (3a) sketched in Figures 9 and 10 presuppose that these two readings **are** the output of interfacing syntax and semantics. Examples of coercion such as (5) are only relevant to the uncovering of the architecture of grammar if the addition of the 'missing' material is believed to be a grammatical matter. If it is not, grammatical nondefault correspondence rules of the kind that rule 4 exemplifies are not needed to rectify the mismatch.

Recent work in computational semantics challenges traditional assumptions about the semantic output of grammars and, as a consequence, has altered the relevance of some of the examples in (2)–(5). A fair amount of work, in particular, challenges the view that the semantic output of grammar rules or constraints is fully specified and argues that this output is underspecified. (Cooper, 1983, is a precursor of that computational work. Philosophers of language and neo-Gricean semanticists have also challenged this view, e.g., Recanati, 1993; Levinson, 2001; some of their conclusions parallel those drawn by computational semanticists.) Two main areas of research have focused on whether scopal relations in sentences such as (3a) are grammatically underspecified and whether semantic type mismatches such as in (5) are resolved grammatically. The results of this research are:

- Many scopal relations may not be determined by grammatical rules or constraints, and their determination might involve postsemantic processes.
- The syntactic relation between a head and a complement (e.g., a verb and its direct object) may not correspond semantically to the relation between a predicate and an argument (even leaving aside quantificational NPs). The corresponding semantic relation may be indirect, as, for example, the relation between a predicate and an argument of an argument of . . . an argument.

The difference between underspecified and fully specified semantic representations can be illustrated using tree diagrams. A fully specified semantic representation can be diagrammed as a set of fully connected trees, as in the case of Figures 6 and 7 for the first-order predicate calculus representations of the two relevant readings of sentence (3a). As discussed earlier, the DSSI hypothesis claims that the relative hierarchical position of the quantifiers in these semantic representations matches that of their syntactic expression at the LF level of analysis (see

Figure 13 The underspecified semantics of sentence (11).

Figures 4 and 5). Similarly, sentence (11) (a slightly more complex version of (3a)) would receive as **one** of its LF analyses under the DSSI hypothesis the tree configuration in Figure 12.

(11) Every man loves a woman.

Underspecified semantic representations, on the other hand, can be diagrammed as a less than fully connected tree. The semantic output of parsing sentence (11), for example, would be a set of three partial trees, as Figure 13 illustrates.

Each treelet in Figure 13 can receive a compositional semantics (alternatively, each rule used to build the treelets can be paired with a semantic rule). The leftmost tree can be interpreted as:

$$\lambda p.(\forall x(\text{man}'(x) \rightarrow p(x)))$$

(the ... in the treelet is translated as a lambda-abstracted variable); the middle tree as:

$$\lambda q.(\exists y(\text{woman}' \wedge q(y)))$$

and the rightmost tree as:

$$\lambda y \lambda x.(\text{love}'(x, y))$$

This is very similar to what proponents of the NLP hypothesis would do: Each such treelet's meaning can be derived through functional application. But the semantic correlate of syntactically combining a verb and its direct object or a VP and its subject is merely the set union of these constituents' meanings. The semantic interpretation of these underspecified meanings is often said to be simply the set of fully connected semantic trees that can be built from these treelets. (Reyle, 1993, provides a possible direct model–theoretic interpretation of underspecified semantic representations.)

Now, because the semantic output of grammars is not a **single** fully connected tree, the structure of the syntactic tree cannot reflect the structure of the semantic representation. Thus, such frameworks can assume a single syntactic structure as the output of the syntactic component of grammars – for example, the tree in Figure 14 for sentence (11), given the

Figure 14 The syntactic structure of sentence (11).

phrase structure rules in (8) – while maintaining a rule-to-rule hypothesis.

The analysis of sentences that involve coercion follows parallel lines. Egg *et al.* (2001), for example, argued that the semantic interpretation of sentences such as (5) does not include additional semantic material (i.e., the direct object is not grammatically interpreted as *drinking the beer* and *reading the book*). Rather, the semantic output is a partial tree specification. The predicate *begin'* is required to dominate the interpretation of its complement (i.e., to include the interpretation of its complement within its second argument), but is not required to **immediately** dominate it, leaving open the possibility that pragmatic processes will interpolate conceptual content between the two. Nonstandard grammatical correspondence rules such as rule 4, whose sole purpose was to interpolate such conceptual content, would now become otiose.

Where Does the Meaning Come From?

Another assumption of the first two hypotheses we have reviewed is that the nature of the meaning carried by a lexical item differs from that encoded by syntactic structures or rules. Words (or morphemes) carry substantive meanings, whereas syntactic structures or rules only serve to combine or put these substantive meanings together. This division of labor is quite clear in the two derivations of sentence (3a) represented in Figures 9 and 10. The meanings of words carry the quantificational and predicative meanings; the rules only fill in the missing arguments in these lexical meanings (providing values for lambda-abstracted variables). Syntactic rules or structures in such a view do not **carry** meaning; they merely glue or combine meanings carried by words or morphemes.

The last 20 years have seen the emergence of another view that holds that syntactic structures **do**

carry meaning, too, at times (see Fillmore *et al.*, 1988; Ginzburg and Sag, 2001, for early and most articulated examples of this line of research). Syntactic structures thus can **both** glue meanings together and/or carry meaning on their own. Convincing evidence that syntactic structures, rules, or constructions carry meaning, is hard to come by because it is almost always possible to assign the meaning assigned to a syntactic construction to some lexical material within the sentence. But Ginzburg and Sag (2001) presented data (see also Huang, 1982) that suggest that syntactic structures do carry meaning. They show that fronting the *wh*-phrase, as English often does, as in (2a), has an effect on meaning. Fronted *wh*-phrases cannot have wider scope than their surface position. In contrast, *wh*-phrases that remain in position are freer in their scoping possibilities. In particular, they can have scope over the matrix clause when a question is embedded after verbs such as *know* and *ask*. The contrast between the Chinese (Mandarin Chinese) sentence in (12) (from Huang, 1982), in which the *wh*-phrase has remained in position, and its two possible interpretations indicated in its English translations illustrates the difference. The English *wh*-phrase has been fronted in both translations, and its scope is determined by its surface position. But the Chinese *wh*-phrase, which remains in place, can vary in scope. The different interpretative possibilities of the Chinese example and its English translations do not seem due to differences in **lexical** meaning between *shei* and its English counterpart *who*. Rather, it seems to follow from the different syntactic structures in which the two words occur (or the operations they undergo), thus suggesting that syntactic structures or rules contribute more to meaning than the glue for (substantive) lexical meanings.

(12) [Zhangsan [zhidao shei mail-le shu]]
Zhangsan know who buy-ASP book
'who does Zhangsan know bought books? /
Zhangsan knows who bought books'

Although much work has been devoted in the last 30 years to developing more precise architectures for the interface between syntax and semantics and finding data that support them, garnering convincing evidence that favors one hypothesis to the exclusion of the others has been hard. The difficulty partly stems from the fact that the proposed models are sufficiently rich to account for most of the data. Choosing among them is, therefore, more a matter of elegance or some intuitive notion of simplicity than sheer descriptive adequacy. Furthermore, research has often focused on existence proofs (proof that some phenomenon can or cannot be accounted by one (version of) a model) or on relatively small grammar fragments for which explicit syntactic and semantic rules or constraints are provided. Two recent trends suggest better model evaluation might soon be available. First, several researchers now use data on human online sentence processing or word access as additional sources of evidence (see Steedman, 2000; Jackendoff, 2002). Second, large-scale implemented grammars that output both semantic and syntactic representations have developed in the last decade and might therefore allow the large-scale testing of the models on a realistic portion of natural languages, such as the ParGram project within Lexical-Functional Grammar and the LinGO project within Head-driven Phrase Structure Grammar.

Acknowledgments

I gratefully acknowledge Juergen Bohnemeyer, David Braun, Karin Michelson, Atsuko Nishiyama, and William Rapaport for their generous comments on a previous draft of this article. All remaining errors are mine.

Syria: Language Situation

J Battenburg, California Polytechnic State University, San Luis Obispo, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Although Arabic is the official language of Syria, considerable linguistic variation exists in the forms of Arabic spoken and also in the wealth of language minority communities represented in the country. Syria has a population of approximately 18 million with a literacy rate of 76%.

Arabic diglossia exists in Syria as in other Arab countries. So-called higher varieties, including Classical Arabic and Modern Standard Arabic, are used alongside what some consider lower colloquial varieties, which themselves are represented by local dialects. North Levantine Arabic (Arabic, North Levantine Spoken) (also referred to as Lebanese-Syrian Arabic) is an urban standard dialect based on the speech of those living in Damascus. North Levantine Arabic is commonly heard in broadcasting. Mesopotamian Arabic (Arabic, North Mesopotamian Spoken), spoken in Eastern Syria, is very similar to many Iraqi varieties of Arabic, while Najdi Arabic (Arabic, Najdi Spoken), spoken in the Syrian desert, is similar to certain varieties of Arabic spoken in Iraq, Jordan, and Saudi Arabia.

Kurdish (Kurmanji) represents the largest language minority community with an estimated 1.5 million speakers. Although Kurdish was used for publication and broadcasting during the French Mandate from 1920 to 1946, today Arabic is used in mass media and educational instruction within the Kurdish community.

South Azerbaijani speakers in Syria, referred to as Turkmen, form a community of 100 000. Circassian (also known as Adyghe) is a North Caucasian language that is spoken by approximately 40 000. Numerous Circassian families have been displaced from villages in the Golan Heights. Domari speakers number approximately 10 000. The Domari, referred to as Muslim Gypsies, trace their origins to India in the 18th century and are spread out in communities in North Africa and the Middle East.

Members of three language minority groups also form a large part of the Christian community in Syria. Armenian is spoken by an estimated 350 000, many who live in and near Aleppo. Armenians work as professionals or in business, small industry, or crafts. Assyrian (Assyrian Neo-Aramaic) (also known as Neo-Syriac) is spoken by approximately 45 000 in 35 villages along the Khabur River, an important tributary of the Euphrates River. Assyrian is lexically influenced by Akkadian, the ancient language of Assyrians and Babylonians; however, it shares considerable similarity

Syriac

G Kiraz, Beth Mardutho: The Syriac Institute, Piscataway, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Syriac is a form of Aramaic, a Semitic language whose many dialects have been in continuous use since the 11th century B.C. Syriac is by far the most attested dialect of Aramaic. It is used today in two forms: Classical Syriac, which is a literary form of the language, and Vernacular Neo-Syriac, which consists of many regional dialects. Syriac is used by Christian communities in the Middle East, known as Syriacs, Assyrians, Chaldeans, and Maronites; and in the Indian state of Kerala, primarily as a liturgical language, by communities known as the St Thomas Christians. There are today only a few hundred speakers of Classical Syriac, fewer than one million speakers of Vernacular Neo-Syriac, but over 10 million who consider Classical Syriac their liturgical language. Classical Syriac exists in two main dialects, West Syriac and East Syriac, the difference between them being minor phonological variations.

Historically, the earliest dated Syriac inscription is from 6 A.D., and the earliest parchment, a deed of sale, is from 243. The earliest dated manuscript was produced in November 411, probably the earliest dated manuscript in any language. Within a few centuries from its origin, Syriac produced a wealth of literature that surpassed all other Aramaic dialects. Early literature was produced in Mesopotamia, especially in and around Edessa, by pagans, agnostics, Jews, and Christians. The literature of the first three centuries consists mostly of anonymous texts whose date and origin cannot be established. The 4th century witnessed the first major writings that survive to this day. The 5th to 9th centuries mark the Golden Age of Syriac, with more than 70 important known authors, not counting numerous anonymous works and lesser authors. These writings cover philosophy, logic, medicine, mathematics, astronomy, alchemy, history, theology, linguistics, and literature. Under the Arabs, Syriac was the vehicle by which the Greek sciences passed to the Muslim world, and later to Europe through Spain, marking Syriac as an important stage in the history of world civilization. As Arabic began to replace Syriac as the primary language of the Middle East, Syriac became less prominent but has continued to be used until today.

The Syriac writing system makes use of three scripts. The oldest, known as Estrangelo 'rounded,' was fully developed by the 5th century. Later, two geographic scripts derived from it: West Syriac, whose proper name is Serto, and East Syriac. Early Syriac writing consists of consonants and long vowels only. In the 7th century, a vocalization system was developed and lent itself to Hebrew and Arabic. At the time of Genghis Khan (12th century), the Mongolian script was derived from Syriac.

The phonology of Syriac makes use of 22 consonants, three of which are *matres lectionis* (glottal stop, *w*, and *y*), and seven vowels (five in the case of West Syriac). Six consonants, known by the mnemonic *bgdkpt*, undergo spirantization, where the plosives become fricatives. Traditionally, stress has been assigned to the penultimate syllable in West Syriac, and the final syllable in East Syriac. Syllabification employs long open (CVV) and closed (CVC) syllables. The short vowel of a CV syllable is almost always deleted.

The morphology of Syriac is based on root-and-pattern morphology, in addition to suffixation,

with Aramaic (Western Neo-Aramaie). Aramaic, with some 15 000 speakers, is facing obsolescence. Although the language of Christ and the lingua franca of the Holy Land 2000 years ago, it is only spoken in three small villages north of Damascus: Maloula, Jabadin, and Bakha. Aramaic is still used in liturgies in Syrian Orthodox and Catholic Churches.

French and English are two foreign languages spoken in Syria. The use of French has decreased and is not used as widely as in neighboring Lebanon, and, as elsewhere in the Arab world, English is slowly spreading due to modernization and privatization.

Syriac

G Kiraz, Beth Mardutho: The Syriac Institute, Piscataway, NJ, USA

Syriac is a form of Aramaic, a Semitic language whose many dialects have been in continuous use since the 11th century B.C. Syriac is by far the most attested dialect of Aramaic. It is used today in two forms: Classical Syriac, which is a literary form of the language, and Vernacular Neo-Syriac, which consists of many regional dialects. Syriac is used by Christian communities in the Middle East, known as Syriacs, Assyrians, Chaldeans, and Maronites; and in the Indian state of Kerala, primarily as a liturgical language, by communities known as the St Thomas Christians. There are today only a few hundred speakers of Classical Syriac, fewer than one million speakers of Vernacular Neo-Syriac, but over 10 million who consider Classical Syriac their liturgical language. Classical Syriac exists in two main dialects, West Syriac and East Syriac, the difference between them being minor phonological variations.

Historically, the earliest dated Syriac inscription is from 6 A.D., and the earliest parchment, a deed of sale, is from 243. The earliest dated manuscript was produced in November 411, probably the earliest dated manuscript in any language. Within a few centuries from its origin, Syriac produced a wealth of literature that surpassed all other Aramaic dialects. Early literature was produced in Mesopotamia, especially in and around Edessa, by pagans, agnostics, Jews, and Christians. The literature of the first three centuries consists mostly of anonymous texts whose date and origin cannot be established. The 4th century witnessed the first major writings that survive to this day. The 5th to 9th centuries mark the Golden Age of Syriac, with more than 70 important known authors, not counting numerous anonymous works and lesser authors. These writings cover philosophy, logic, medicine, mathematics, astronomy, alchemy, history, theology, linguistics, and literature. Under the Arabs, Syriac was the vehicle by which the Greek sciences passed to the Muslim world, and later to Europe through Spain, marking Syriac as an important stage in the history of world civilization. As Arabic began to replace Syriac as the primary language of the Middle East, Syriac became less prominent but has continued to be used until today.

The Syriac writing system makes use of three scripts. The oldest, known as Estrangelo 'rounded,' was fully developed by the 5th century. Later, two geographic scripts derived from it: West Syriac, whose proper name is Serto, and East Syriac. Early Syriac writing consists of consonants and long vowels only. In the 7th century, a vocalization system was developed and lent itself to Hebrew and Arabic. At the time of Genghis Khan (12th century), the Mongolian script was derived from Syriac.

The phonology of Syriac makes use of 22 consonants, three of which are *matres lectionis* (glottal stop, *w*, and *y*), and seven vowels (five in the case of West Syriac). Six consonants, known by the mnemonic *bgdkpt*, undergo spirantization, where the plosives become fricatives. Traditionally, stress has been assigned to the penultimate syllable in West Syriac, and the final syllable in East Syriac. Syllabification employs long open (CVV) and closed (CVC) syllables. The short vowel of a CV syllable is almost always deleted.

The morphology of Syriac is based on root-and-pattern morphology, in addition to suffixation,

prefixation, and circumfixation. Most roots consist of three consonants, although two- and four-consonantal roots exist. Roots that do not contain any of the *matres lectionis* are called 'strong,' and those containing *matres lectionis* are called 'weak' and for the most part undergo various phonological processes. Most words are derived according to a CV template and a vocalism.

Verbs exist in two tenses: perfect, denoting past tense, marked by zero or one suffix; and imperfect, denoting future tense, marked by a circumfix. The imperative is marked by the suffix part of the imperfect circumfix. Closely related to verbs are the participles and the infinitive. Verbal affixes mark number (singular, plural), person (1st, 2nd, 3rd), and gender (masculine, feminine).

Nouns exist in three states: 'absolute' is the basic form and in early Syriac used to indicate nondetermination; 'emphatic,' by far the most frequent, is marked by a gender-sensitive suffix and is used to mark determination; and 'construct' (joining two nouns) is used primarily to mark a genitive like relation. Adjectival forms are formed mostly by one or more suffixes, those with fewer suffixes belonging to earlier periods of the language. More complex nouns are formed by formative prefixes, and may also contain suffixes.

Personal pronouns either stand on their own, or are in the form of suffixes; they are also either in subject form or object form. Demonstrative and interrogative pronouns stand alone. The relative pronoun is in the form of a prefix.

The sentence structure does not put hard constraints on word or clause order, though idiomatic construction is not very free. Nominal sentences have a noun, an adjective, or an adverbial expression as a predicate. Copulative sentences are joined together with a conjunction in the form of a prefix (in the case of 'and') or a stand-alone word (in the case of 'or'). Syriac also uses relative clauses, marked by the prefix *d*, indirect interrogative clauses, marked by a particle, and conditional clauses, also marked by a particle.

The Syriac lexicon is either arranged by root, or in a quasialphabetical order (in the latter case, derivations of the verb with prefixes appear in the unprefixed 3rd singular masculine form). The primary Syriac lexica in use were all composed in the 19th and early 20th centuries.

Systematicity

P Robbins, Washington University in St. Louis, St. Louis, MO, USA

It is something of a commonplace that linguistic capacities are systematic: very roughly, that understanding a sentence entails understanding certain other sentences related to the first. Likewise, it is something of a commonplace that the best way to account for this fact is by supposing that linguistic meaning is compositional: again roughly, that to understand a sentence, it suffices that one understand the meanings of the words it contains and its syntactic structure. This explanatory hypothesis in turn accounts for much of the reason why compositionality is widely regarded by linguists and philosophers of language as a bedrock constraint on theories of meaning. But the real story about systematicity is rather more complicated. To begin with, the term 'systematicity' is far from univocal. A quick glance at the philosophical literature in which it has figured so prominently in recent years reveals at least three different senses of the term in common use. Since only confusion can result from running these different senses together, we will start by distinguishing them. Then we will assess the plausibility of various systematicity claims and their broader theoretical significance, giving special attention to the question of compositionality.

prefixation, and circumfixation. Most roots consist of three consonants, although two- and four-consonantal roots exist. It is something of a commonplace that linguistic capacities are systematic: very roughly, that understanding a sentence entails understanding certain other sentences related to the first. Likewise, it is something of a commonplace that the best way to account for this fact is by supposing that linguistic meaning is compositional: again roughly, that to understand a sentence, it suffices that one understand the meanings of the words it contains and its syntactic structure. This explanatory hypothesis in turn accounts for much of the reason why compositionality is widely regarded by linguists and philosophers of language as a bedrock constraint on theories of meaning. But the real story about systematicity is rather more complicated. To begin with, the term 'systematicity' is far from univocal. A quick glance at the philosophical literature in which it has figured so prominently in recent years reveals at least three different senses of the term in common use. Since only confusion can result from running these different senses together, we will start by distinguishing them. Then we will assess the plausibility of various systematicity claims and their broader theoretical significance, giving special attention to the question of compositionality.

Some Varieties of Systematicity

The first and arguably primary notion of systematicity concerns the capacity to process language. More specifically, our linguistic capacity is processing-systematic (p-systematic, for short) if and only if the capacity to understand (know the meaning of) a sentence s in a language L confers the capacity to understand (know the meaning of) a range of sentences $s_1^* \ldots s_n^*$ in L such that each s_i^* is structurally related to s in an appropriate way (Fodor and Pylyshyn, 1988; Hadley, 1994; Cummins, 1996). For example, anyone who understands the sentence *John loves Mary* thereby also understands the sentences *Mary loves John*, *John loves John*, and *Mary loves Mary*. The latter three sentences are appropriately structurally related to the first sentence in virtue of the fact that each of the three sentences can be transformed into the first sentence by permuting or substituting co-occurring words of the same grammatical category (here, the proper nouns *John* and *Mary*). A broader notion of p-systematicity can be arrived at by dropping the co-occurrence restriction, allowing for the substitution of co-categorical words not contained in the initial sentence. Structural relatives of *John loves Mary* in this more liberal sense include, in increasing order of distance, sentences like *John loves Elvis*, *Mary kicks Bridget*, and *Fred bombs Falluja*. The corresponding, stronger p-systematicity claim states that understanding a sentence s confers the capacity to understand a range of sentences $s_1^* \ldots s_n^*$ such that each s_i^* is structurally related to s in the sense described above, and each word occurring in s_i^* is contained in the speaker-hearer's lexicon.

According to a second sense of the term, systematicity is a property of language itself, rather than a property of linguistic understanding. Since systematicity of this sort has to do with the expressive power of language, as opposed to the processing power of language users, we'll call it representation-systematicity. The basic idea is analogous to the notion of systematicity with which we began: a language L is representation-systematic (r-systematic) if and only if L can express a proposition p provided that L can express a range of propositions $p_1^* \ldots p_n^*$ such that each p_i^* is structurally related to p in an appropriate way (Fodor and Lepore, 1991). The relevant structural relation on propositions can be illustrated with the same examples used above. Assuming L is r-systematic, if the proposition that *John loves Mary* is expressible in L, then so are the trio of propositions that *Mary loves John*, that *John loves John*, and that *Mary loves Mary*. Each member of the trio is structurally related to the initial proposition (that *John loves Mary*) because each can be transformed into the latter by permutation or substitution of co-occurring constituents expressed by words of the same grammatical category. As before, the class of propositions structurally related to the initial proposition can be expanded to include the propositions that *John loves Elvis*, that *Mary kicks Bridget*, and so on, by dropping the co-occurrence constraint on constituents. According to the strengthened r-systematicity thesis, a language can express a proposition p only if it can express a range of propositions $p_1^* \ldots p_n^*$, where each p_i^* is structurally related to p in the manner described above, and each constituent of p_i^* is expressible by a word in the language.

Finally, a third notion of systematicity – what we will call grammar-systematicity – also denotes a property of language, but a different property than the one just described. Whereas representation-systematicity is a metasemantic property, grammar-systematicity has a broader metalinguistic scope, encompassing both syntax and semantics. A language L is grammar-systematic (g-systematic) if and only if s is a grammatical sentence of L provided that any s^* structurally related to s is a grammatical sentence of L (Johnson, 2004). Since the relevant notion of structural relatedness between sentences is the same as that implicated in the definition of processing-systematicity, the same examples will serve. The fact that *John loves Mary* can be transformed without loss of grammaticality by permuting or substituting words of the same category, whether drawn from that sentence or from elsewhere in the lexicon, supports the claim that English is g-systematic.

Claims to the effect that natural language is systematic in any of these three ways – processing based, representation based, and grammar based – have a good deal of face plausibility. But before evaluating such claims, we need to scrutinize the above definitions more closely. In particular, we need to consider what it is for two words to belong to the same grammatical category. Pending some clarification of this issue, the concept of structural relatedness, and with it the very idea of systematicity, will remain somewhat obscure (Johnson, 2004). And a non-circular (i.e., systematicity independent) standard of sameness of category is not easy to formulate. Even the relatively fine-grained category of proper nouns, for example, seems too heterogeneous to support a robust claim of systematicity, as witnessed by the sentence *Julia sang the lead in 'West Side Story'* and its anomalous permutational variant *'West Side Story' sang the lead in Julia*. Given the plurality of constraints – syntactic, semantic, and phonological – on lexical substitution, better candidates for grammatical

category-hood are going to be hard to come by (Harris, 1951).

How deep a problem this amounts to, however, depends to some extent on what notion of systematicity one is working with. In the case of grammar-systematicity, for example, the difficulty seems serious enough to warrant skepticism about the substance of the claim that language is g-systematic (Johnson, 2004). Processing-systematicity, on the other hand, is a different story. Since it is impossible to understand an anomalous sentence, it is plausible to suppose that understanding a sentence confers understanding of any structural variant of that sentence, provided that the variant in question is interpretable at all. Similar considerations apply to the case of representation-systematicity (Fodor and Lepore, 1991). It is plausible to suppose that the capacity of language to express a proposition entails the capacity to express any structural variant of that proposition, provided that the variant in question exists and is not anomalous. But this sort of strategy seems to be unavailable in the case of grammar-systematicity. Obviously, it won't do to say 'The structural variants of a grammatical sentence are grammatical, unless they are not.'

Be that as it may, it remains plausible that language is systematic in all three of the ways canvassed above, at least to a modest extent. Consider the following theses:

- *Minimal p-systematicity.* Understanding a sentence *s* entails understanding some structural variants of *s*.
- *Minimal r-systematicity.* If a language *L* can express a proposition *p*, then *L* can express some structural variants of *p*.
- *Minimal g-systematicity.* If *s* is a grammatical sentence, then some structural variants of *s* are grammatical.

Systematicity claims of this sort are hard to resist, given the apparent ease of generalization from the case of *John loves Mary* and its close variants. Whether language is p-systematic, r-systematic, or g-systematic in any stronger sense (e.g., whether 'many' can be strengthened to 'all') is an open question. But for the purposes of addressing the question of compositionality in natural language, these weak claims are enough to start with.

Explaining Systematicity

The idea that language is compositional, like the idea that language is systematic, can be formulated in various ways (*see* **Compositionality: Semantic Aspects**). According to one version, the principle of compositionality is a claim about our semantic competence, namely, that understanding the words in a sentence and the syntax of the sentence typically suffices for understanding the sentence. This is epistemic compositionality (e-compositionality). On another, more metaphysical, construal, the principle concerns language itself. It says that the meaning of a sentence typically supervenes on the meanings of the words in the sentence plus its syntax. We will call this ontic compositionality (o-compositionality). As noted above, systematicity is widely cited as a reason to believe in such principles. The connection between them, however, is more complex and attenuated than it may first appear. To start with, both e-compositionality and o-compositionality have to do mostly with semantics, and nothing else. As a result, considerations of g-systematicity, a broadly metalinguistic property, are of little significance. Instead, an argument to the best explanation from systematicity to compositionality will take one of two forms: either from p-systematicity to e-compositionality, or from r-systematicity to o-compositionality.

The line of argument from r-systematicity to o-compositionality is straightforward. We begin by assuming that a language *L* expresses the proposition *p*. This is equivalent to the claim that there is a sentence *s* in *L* that expresses *p*. According to compositionality, the meaning of *s* is determined by the meanings of the words in *s* plus the syntax of the sentence. The same goes for structural variants of *s*, the meaning of which will be structural variants of *p*. If we suppose that *L* is compositional, then we get a ready explanation of the fact that *L* expresses a proposition *p* only if it expresses structural variants of *p*.

The line of argument from p-systematicity to e-compositionality is trickier. In order for the supposition that semantic competence is compositional to explain why that competence is systematic, it should follow from that supposition that the competence in question is systematic. But this is patently not the case. Assume that you understand a sentence *s*. The goal is to infer from this assumption that you understand structural variants of *s* as well. But the principle of e-compositionality says only that understanding the words and syntax of *s* suffices for understanding *s*; it does not say that understanding *s* suffices for understanding the words and syntax of *s*. Yet the latter assumption – the principle of reverse compositionality (Fodor and Lepore, 2001; Fodor, 2002) – is precisely what is needed in order to conclude, via the principle of compositionality, that understanding a sentence entails understanding its

permutational variants. The amended argument is straightforward. If you understand *s*, then by reverse compositionality, you understand the syntax of *s* and the words occurring in *s*. These words can be re-ordered, *modulo* categorial constraints, within that syntactic structure to yield permutational variants of *s*. By compositionality, since you understand the words and syntactic structure of those variants, you also understand the variants. Hence, even if linguistic competence were compositional, that alone would not explain why it is systematic; one also needs to assume that it is reverse compositional.

A natural response to make at this juncture is that the phenomenon of p-systematicity warrants both e-compositionality and reverse e-compositionality. One problem with this move, however, is that the principle of reverse compositionality is probably false (Robbins, forthcoming). At a minimum, every theory of meaning on the market today, including the most austere versions of truth-conditional semantics, is incompatible with it (*see* **Meaning: Overview of Philosophical Theories**). For example, it's possible to know the truth-conditions of the sentence *Pet fish have tails* without knowing that *pet* refers to pets and *fish* refers to fish. All one needs to know about the NP *pet fish* is that it refers to pet fish, and that fact is consistent with the assumption that *pet* refers to fish and *fish* refers to pets. Hence, if the truth-conditionalist story is correct, one can know the meaning of *Pet fish have tails* without knowing the meanings of *pet* and *fish*. And non-truth-conditional accounts of meaning are in the same boat.

What's needed to escape this quandary, it seems, is a slight weakening of the thesis of minimal p-systematicity. Rather than saying that understanding a sentence strictly necessitates understanding some of its structural variants, we might say instead that instances of the first type of understanding are typically accompanied by instances of the second type. Such a pattern can be readily explained by the principle of compositionality together with a similarly watered-down form of reverse compositionality, according to which understanding a sentence is typically accompanied by an understanding of its syntax and the words contained therein. This in turn reveals how the systematicity of our semantic competence, however minimal in extent, militates in favor of its being compositional.

Origins of Systemic Theory

Systemic, or systemic–functional, theory has its origin in the main intellectual tradition of European linguistics that developed following the work of Saussure (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913); Saussurean Tradition in 20th-Century Linguistics**). Like other such theories, both those from the mid-twentieth century (e.g., Prague school (*see* **Prague School**); French functionalism) and more recent work in the same tradition (e.g., that of Hagège), it is functional and semantic rather than formal and syntactic in orientation, takes the text rather than the sentence as its object, and defines its

permutational variants. The amended argument is straightforward. If you understand *s*, then by reverse compositionality, you understand the syntax of *s* and the words occurring in *s*. These words can be reordered, *modulo* categorial constraints, within that syntactic structure to yield permutational variants of *s*. By compositionality, since you understand the words and syntactic structure of those variants, you also understand the variants. Hence, even if linguistic competence were compositional, that alone would not explain why it is systematic; one also needs to assume that it is reverse compositional.

A natural response to make at this juncture is that the phenomenon of p-systematicity warrants both e-compositionality and reverse e-compositionality. One problem with this move, however, is that the principle of reverse compositionality is probably false (Robbins, forthcoming). At a minimum, every theory of meaning on the market today, including the most austere versions of truth-conditional semantics, is incompatible with it (*see* **Meaning: Overview of Philosophical Theories**). For example, it's possible to know the truth-conditions of the sentence *Pet fish have tails* without knowing that *pet* refers to pets and *fish* refers to fish. All one needs to know about the NP *pet fish* is that it refers to pet fish, and that fact is consistent with the assumption that *pet* refers to fish and *fish* refers to pets. Hence, if the truth-conditionalist story is correct, one can know the meaning of *Pet fish have tails* without knowing the meanings of *pet* and *fish*. And non-truth-conditional accounts of meaning are in the same boat.

What's needed to escape this quandary, it seems, is a slight weakening of the thesis of minimal p-systematicity. Rather than saying that understanding a sentence strictly necessitates understanding some of its structural variants, we might say instead that instances of the first type of understanding are typically accompanied by instances of the second type. Such a pattern can be readily explained by the principle of compositionality together with a similarly watered-down form of reverse compositionality, according to which understanding a sentence is typically accompanied by an understanding of its syntax and the words contained therein. This in turn reveals how the systematicity of our semantic competence, however minimal in extent, militates in favor of its being compositional.

Systemic Theory

M A K Halliday

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 8, pp. 4505–4508, © 1994, Elsevier Ltd.

Origins of Systemic Theory

Systemic, or systemic–functional, theory has its origin in the main intellectual tradition of European linguistics that developed following the work of Saussure (*see* **Saussure, Ferdinand (-Mongin) de (1857–1913); Saussurean Tradition in 20th-Century Linguistics**). Like other such theories, both those from the mid-twentieth century (e.g., Prague school (*see* **Prague School**); French functionalism) and more recent work in the same tradition (e.g., that of Hagège), it is functional and semantic rather than formal and syntactic in orientation, takes the text rather than the sentence as its object, and defines its

scope by reference to usage rather than grammaticality. Its primary source was the work of J. R. Firth and his colleagues in London (*see* **Firth and the London School**). As well as other schools of thought in Europe such as glossematics it also draws on American anthropological linguistics, and on traditional and modern linguistics, and on traditional and modern linguistics as developed in China.

Its immediate source is as a development of scale and category grammar. The name 'systemic' derives from the term 'system,' in its technical sense as defined by Firth (1957); system is the theoretical representation of paradigmatic relations, contrasted with 'structure' for syntagmatic relations. In Firth's system–structure theory, neither of these is given priority; and in scale and category grammar this perspective was maintained. In systemic theory the system takes priority; the most abstract representation at any level is in paradigmatic terms. Syntagmatic organization is interpreted as the 'realization' of paradigmatic features.

This step was taken by Halliday in the early 1960s so that grammatical and phonological representations could be freed from constraints of structure. Once such representations were no longer localized, they could function prosodically wherever appropriate. The shift to a paradigmatic orientation added a dimension of depth in time, so making it easier to relate language 'in use' to language being learnt; and it enabled the theory to develop both in reflection and in action – as a resource both for understanding and for intervening in linguistic processes. This potential was exploited in the work done during the 1960s on children's language development from birth through their various stages of schooling.

Systems and Their Realization

The organizing concept of a systemic grammar is that of choice (that is, options in 'meaning potential'; it does not imply intention). A system is a set of options together with a condition of entry, such that if the entry condition is satisfied one option, and one only, must be chosen; for example, in English grammar, [system] 'mood,' [entry condition] finite clause, [options] indicative/imperative. The option selected in one system then serves as the entry condition to another; e.g., [entry condition] indicative, [options] declarative/interrogative; hence all systems deriving from a common point of origin (e.g., [clause]) are agnate and together form a 'system network.' At the present stage of development, system networks for English grammar in computational form contain about 800 systems. An entry condition may involve the conjunction of different options; hence a system network is not a taxonomic structure but has the form of a lattice.

The system has one further component, namely the 'realization statement' that accompanies each option. This specifies the contribution made by that option to the structural configuration; it may be read as a proposition about the structural constraints associated with the option in question. Realization statements are of seven types:

1. 'Insert' an element (e.g., insert subject);
2. 'Conflate' one element with another (e.g., conflate subject with theme);
3. 'Order' an element with respect to another, or to some defined location (e.g., order finite auxiliary before subject);
4. 'Classify' an element (e.g., classify process as mental: cognition);
5. 'Split' an element into a further configuration (e.g., split mood into subject + finite);
6. 'Preselect' some feature at a lower rank (e.g., preselect nominal group: human collective); and
7. 'Lexify' an element (e.g., lexify subject: *it*).

When paths are traced through a system network, a 'selection expression' is formed consisting of all the options taken up in the various functional components. As the network is traversed, options are inherited, together with their realizations; at the same time, new realization statements continue to figure throughout. The selection expression constitutes the grammar's description of the item (e.g., the particular clause so specified); it is also, by reference to the network, the representation of its systemic relationship to other items in the language – since the grammar is paradigmatic, describing something 'consists in' locating it with respect to the rest (showing its total lineage of agnate forms).

Other Basic Concepts

Systemic theory retains the concepts of 'rank,' 'realization,' and 'delicacy' from scale and category grammar. 'Rank' is constituency based on function, and hence 'flat,' with minimal layering; 'delicacy' is variable paradigmatic focus, with ordering from more general to more delicate; 'realization' (formerly 'exponence') is the relation between the 'strata,' or levels, of a multistratal semiotic system – and, by analogy, between the paradigmatic and syntagmatic phases of representation within one stratum. But in systemic theory, realization is held distinct from 'instantiation,' which is the relation between the semiotic system (the 'meaning potential') and the

observable events, or 'acts of meaning,' by which the system is constituted.

The shift to a paradigmatic orientation led to the finding that the content plane of a language is organized in a small number of functionally defined components which Halliday labeled 'metafunctions.' According to this theory the grammar of natural languages evolved in simultaneously (a) 'construing' human experience (the 'experiential' metafunction) and (b) 'enacting' interpersonal relationships (the 'interpersonal' metafunction), both these being underpinned by (c) the resources of (commonsense) logic (the 'logical' metafunction; (a) and (c) are grouped together as 'ideational'). The stratal role of the lexicogrammar lies in mapping these semantic components into a unitary construct, one that is capable of being linearized; in doing this, the grammar (d) 'creates' its own parallel universe in the form of discourse (the 'textual' metafunction). These metafunctions define the dimensions of semantic space; and since they tend to be realized by different structural resources – experiential meanings segmentally, interpersonal meanings prosodically, logical meanings in iterative structures, and textual meanings in wave-like patterns – they also determine the topological formations that are characteristic of human speech.

A systemic grammar is therefore 'functional' is three distinct though related senses:

1. Its 'explanations' are functional: both the existence of grammar (why grammar evolved as a distinct stratum), and the particular forms that grammars take, are explained in terms of the functions that language evolved to serve.
2. Its 'representations' are functional: a structure is an organic configuration of functions, rather than a tree with nodes labeled as classes.
3. Its 'applications' are functional: it developed as an adjunct to practices associated with language use, requiring sensitivity to functional variation in language ('register' variation). These considerations both relate it to, and at the same time distinguish it from other functional theories.

Other Features of the Theory

Like the Firthian linguistics from which it evolved, systemic theory is oriented towards language as social process; the individual is construed intersubjectively, through engagement in social acts of meaning. This is not incompatible with a cognitive perspective, which has been adopted in some systemic work (notably Fawcett 1980); but it does rule out any claim for 'psychological reality.' Halliday formulated this general stance as 'language as social semiotic,' thereby also locating systemic theory in the thematic context of semiotics, defined as the study of systems and processes of meaning. The relation between language and other sociocultural phenomena is then modeled on that of realization (the perspective here is Firthian rather than Hjelmslevian; *see* **Hjelmslev, Louis Trolle (1899–1965)**): language 'realizes' culture in the way that, within language, sound realizes wording, and the realization of wording in sound, in its turn, realizes meaning.

It follows from this that systemic theory gives prominence to discourse, or 'text'; not – or not only – as evidence for the system, but valued, rather, as constitutive of the culture. The mechanism proposed for this constitutive power of discourse has been referred to as the 'metafunctional hookup': the hypothesis that (a) social contexts are organic–dynamic configurations of three components, called 'field,' 'tenor,' and 'mode': respectively, the nature of the social activity, the relations among the interactants, and the status accorded to the language (what is going on, who are taking part, and what they are doing with their discourse); and (b) there is a relationship between these and the metafunctions such that these components are construed, respectively, as experiential, as interpersonal, and as textual meanings. Register, or functional variation in language, is then interpreted as systemic variation in the relative prominence (the probability of being taken up) of different options within these semantic components.

In fact such register variation (spoken/written, commonsense/technical, transactional/expository, . . . and so on) lies on the continuum between system and text; the characteristic of systemic work is that it brings all parts of this continuum under focus of attention. Analogously, it encompasses both speaker and listener perspectives (in computational terms, text generation, and parsing – there are, for example, no nonrecoverable operations such as deletion), and both synoptic and dynamic orientations; and uniquely among current theories, it assigns as much value to interpersonal and textual meaning as to ideational. On the other hand, in other respects systemic work is notably ill-balanced; there has been little study of morphology and phonology, and a disproportionate amount of research relates to English. These reflect on the one hand the contexts of its own development, especially the kinds of application for which it has been sought out; and on the other hand its requirement of comprehensiveness, demanding a coverage which is at once both broad and deep.

Development of Systemic Theory

The outlines of systemic theory were formulated in London in the 1960s by Halliday together with Huddleston, Hudson, and others, and others, and in application to Bernstein's work by Hasan, Mohan, and Turner; other significant input came from the application of systemic concepts in curriculum development work, in the analysis of scientific writings and of natural conversation, and in descriptions of a number of Asian and African languages. The theory was further developed in the 1970s: by Fawcett, Berry, and Butler in the UK; by Halliday and Hasan; and by Gregory and his colleagues in Toronto. Since 1980 systemic work has expanded considerably in various directions (artificial intelligence, child language development, discourse analysis and stylistics, and language education). It is typical of systemic practice that major extensions both to description and to theory have taken place in these 'applied' contexts; for example, the very large systemic grammars of English that now exist in computational form (PENMAN 'Nigel'; COMMUNAL), and the extensive studies of children's writing and of the language of educational texts in science, history, and other subjects that have been carried out by Martin and his colleagues in contexts such as the New South Wales Disadvantaged Schools Program.

Since 1980, further studies have been devoted to languages other than English, notably Chinese (Fang; Hu; Long; McDonald; Ouyang; Zhang; Zhao; Zhu), French (Caffarel), Indonesian (Sutjaja; Wirnani), and Tagalog (Martin); and work in text generation has begun to take in Chinese and Japanese (Matthiessen *et al.,*) and German, French, and Dutch (Bateman; Steiner). In English, Halliday's *Introduction to Functional Grammar* brought together some of his studies begun in the late 1960s (1967/68); and advances were made in all areas of the grammar: experiential (Davidse; Martin), interpersonal (Butler; Thibault), and textual (Fries; Hasan; Matthiessen). Matthiessen (1992a) presented a system-based account of English grammar, deriving from materials he had written to accompany the 'exporting' of Nigel.

Many general theoretical discussions have appeared (Fawcett; Halliday; Lemke, etc.), as well as new theoretical underpinning of key areas, especially lexicogrammar, discourse semantics (*see* **Discourse Semantics**), and text structure (Matthiessen; Martin; Berry; Hasan, etc.). Matthiessen's (1992b) account of register theory emphasizes the integrative character of systemic work: while there are often alternative interpretations, especially where new problems are being addressed, these are not detached from their overall context in language and in linguistics. Thus there is no disjunction between grammar and discourse, or between the system and the text.

With the strengthening of what Halliday calls the 'grammatics' (that is, theory of grammar as metatheoretic resource), systemic writings have increasingly foregrounded the constructive power of grammar; this is reflected in numerous studies which began with the 'critical linguistics' of the late 1970s (Fowler *et al.*; Kress and Hodge; subsequently Butt; Hasan; Kress; Lemke; Martin; McGregor; O'Toole; Thibault; Threadgold; cf. Threadgold *et al.,* 1986, and the new journal *Social Semiotics*). In a large-scale investigation of natural conversation between mothers and their preschool children, Hasan and Cloran (1990) have developed semantic networks to explore the effects of social factors on children's learning styles, and their consequences for education. Martin's work on register and genre (1992) extends the constructivist model of language to include strata of genre and ideology. It is in this overall perspective that language becomes central to the educational initiatives of Martin, Rothery, Christie, and others in Australia; compare also the work of Carter *et al.* in the LINC ('Language in the National Curriculum') program in the UK.

In 1974 Fawcett organized the first systemic workshop, at the West Midlands College of Education, with 16 participants from four centers in the UK. Since then the workshop has been an annual event; the first international workshop was the ninth, held in Toronto (York University) in 1982. In the 1990s, now as 'International Systemic (or Systemic–Functional) Congress,' meetings have been held at the University of Stirling (1990) and at the International Christian University in Tokyo (1991); in addition, regular national systemics seminars are held in Australia, in the UK, and in China. The newsletter *Network* provides information on these activities, along with short articles, reviews, bibliographies, and conference reports. The regularly updated *Select Bibliography of Systemic Linguistics* now lists about 800 books and articles. Selected conference papers from 1983, 1985, 1986, 1988, 1989, and 1990 have appeared in published form (see Bibliography).

Influences and Trends

In the period from its inception in the early 1960s the main influences on systemic theory (other than those coming in via specific applications such as computational linguistics) have come from Lamb's work in stratificational grammar and from Sinclair's in discourse and in lexical studies. Lamb and Halliday collaborated regularly over a number of years. Sinclair had been an originator of scale and category

grammar and his subsequent work exploited this, though in a complementary direction to Halliday's: Sinclair builds the grammar out of the lexis, whereas Halliday builds the lexis out of the grammar. Other input has come from Labov's quantitative methodology (though not his general perspective on language and society; *see* **Labov, William (b. 1927)**); from the theory and practice of corpus linguistics (Quirk (*see* **Quirk, Charles Randolph, Professor Lord (b. 1920)**); Svartvik *et al.*; more recently Sinclair); from other work in functional linguistics (especially Thompson); and from poststructuralist semiotics in general.

A feature of systemic work is that it has tended to expand by moving into new spheres of activity, rather than by reworking earlier positions. This reflects an ideological perspective in which language is seen not as unique or *suigeneris* but as one aspect of the evolution of humans as sociocultural beings. Thus input often comes from outside the discipline of linguistics: from current theories in fields such as anthropology, literature, and neurology, and from developments in more distant sciences. Much systemic linguistics reflects transdisciplinary rather than disciplinary thinking in its approach to problems of language.

This orientation appears in some present trends and likely future directions.

For example:

- Systemic grammatics as model for other semiotic systems, especially forms of art: not only literature (Butt; O'Toole; Thibault; Threadgold) but also music (van Leeuwen; Steiner), visual imagery (Kress and van Leeuwen), and painting, architecture, and sculpture (O'Toole).
- Further developments of register theory to investigate the linguistic construction of knowledge and structures of power.
- Using available corpus data and programs to test hypotheses about the probabilistic properties of systems (Nesbitt and Plum; Halliday and James).
- Further development of language-based educational programs, in initial literacy, secondary 'subjects,' teacher education, language in the workplace, etc.
- Natural language processing, modeling systems of meaning (knowledge systems), and developing integrated generation and parsing programs, including multilingual ones.
- Further work in deaf sign (Johnston) and development of systemic research in neurolinguistics and the discourse of aphasia, dementia, etc.
- Greater emphasis on studies of the expression plane in a general systemic context.

Just as systemic theory is itself a variant of a broader class of theories (functional theories, perhaps with 'system-structure theories' as an intermediate term), so it itself accommodates considerable variation. Gregory's 'communication linguistics' foregrounds structures of knowledge and presents a dynamic 'phase and transition' model of discourse; Fawcett's computational modeling contrasts in various ways with that of Matthiessen and Bateman; Martin's register theory, with genre as a distinct stratum, contrasts with Hasan's view of register as functional variation realizing different values of contextual variables. This kind of variation in 'metaregister' is one of many ways in which systemic theory appears as a metaphor for language itself.

The standard introduction to systemic linguistics has been Berry (1976/77). Other introductory or summary works are Monaghan (1979), Halliday and Martin (1981), Butler (1985), Morley (1985), and, an original work in Chinese, Hu *et al.* (1989). The work now appearing with the New South Wales Disadvantaged Schools Program is an excellent source for the systemic grammar of English, as also is Butt *et al.* (1990–); other workbooks are in the course of preparation. Three further introductory studies that are largely completed are Halliday and Matthiessen, on the history of systemic linguistics; Matthiessen and Halliday, a general account; and Thibault, on grammar and discourse. These will give an overview of theory and practice as current in the mid-1990s.

This article is reproduced from the previous edition, volume 8, pp. 4508–4509, © 1994, Elsevier Ltd.

Oswald Szemerényi was born in London on September 7, 1913 but taken to Budapest on the outbreak of war and brought up in Hungary. He had a brilliant university career and was appointed to the Chair of Indo–European Linguistics at Budapest in 1947. After the war he at first actively supported Communist reforms, but was alienated by subsequent events and took the opportunity of a stay in the Collegium Hungaricum in Rome to apply for repatriation to England, where he came with his wife and son in 1948.

He worked for the BBC and Reuters, and then held a number of university posts in London from 1952 onward; he was appointed Reader in Greek at Bedford College in 1957, and Professor of Comparative Philology at University College in 1960. Here he flourished for another five years; but the limited

interest shown in the subject in London was partly responsible for his accepting an offer of a similar appointment in Freiburg, which he held until his retirement in 1981. He was elected a Fellow of the British Academy in 1982.

Szemerényi's approach to his subject, both in research and teaching, is data-led rather than theory-driven. Characteristic emphases are that:

1. the comparatist needs a first-hand knowledge of a wide range of Indo–European languages;
2. this knowledge is the springboard for a two-way process of reconstruction: the way up from the daughter languages to the parent language is made possible by the comparative method; and the way down from the parent language to the daughter languages (i.e., the reconstruction of outlines of the prehistory of a given language) then becomes a matter of inference;
3. the reconstructions are attempts to recover linguistic reality; although capable of refinement, they are not merely summaries of observed correspondences;
4. descriptive study logically takes precedence over historical; the 'concept of language as a system of systems' and linguistic typology are of particular importance to the comparatist.

The principles are stated in his London inaugural lecture of 1960, *Trends and tasks in comparative philology*, and put to further use in the Freiburg inaugural of 1966, *The New look of Indo–European*, in which a combination of comparative method and linguistic typology leads him to reject the prevailing orthodoxy that the parent language possessed three or four 'laryngeals' (*h*-type sounds) and only a single vowel *e*, and to argue for a single *h* and normal five-vowel system *a e i o u*. His position on this as on many other questions may be termed 'radical conservative,' and the subject has benefited from his challenge to a number of neoorthodoxies.

His principal books are listed below. The four volumes of *Scripta minora* bring together much of his other best known and most important work, including a host of etymological studies, which together constitute one of his most impressive achievements. It is a serious loss to the subject that the *Introduction to Indo–European philology*, conceived on a larger scale than the *Einführung*, has had to be abandoned; but see the bibliography in 1991a. There are full bibliographies in Szemerényi 1987 (by subject) and 1991b (chronological), and an autobiography (1991b).

Taboo

I N Rashkow, State University of New York, Stony Brook, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The main biblical 'taboos' involve sex and food, although there are other prohibitions as well. Leviticus (Chapter 12 and following) is primarily a code of moral and ritual laws whose motivation is 'holiness.' Since a major concern of the writers of the Levitical text seems to have been the creation of rules that would shape the identity of the emerging nation, these passages state over and over again a claim that the Israelites are 'different' than the surrounding cultures. As a result, they established rules by which Israelites could and should define themselves.

Within the biblical construct, segregation of both persons *and* things is a primary consideration. For instance, Leviticus 19:19 prohibits the wearing of cloth combining wool and linen. This prohibition is considered a prime example of a divine statute that has no rational explanation, and Jewish philosophers have attempted to rationalize its intent. Since biblical writings emphasize the differences between the Israelite community and all others, prohibitions against and penalties for illicit relations, homicidal cult practices, and magic probably exist for the same reason as the cloth and food prohibitions: separation and distinction from the neighboring tribes whose perceived idolatrous and immoral practices were to be avoided. The verses that deal with illicit sexual relations, for example, are encased by an introduction that castigates the Egyptians and Canaanites for the depravity of their sexual practices. Total destruction and exile is the threat if these laws are not followed.

The list of prohibited sexual relations begins with the prohibition against a man 'uncovering the nakedness' of his father, followed by 12 categories of forbidden *females*:

- Mother
- Father's wife, brother's wife, and uncle's wife
- Maternal and/or paternal sister
- Son's or daughter's daughter or daughter-in-law
- Stepmother's daughter by the same father
- Paternal or maternal aunt
- Woman and her daughter (and their female descendants) and woman and her sister.

Other sexual prohibitions follow:

- Intercourse with menstruating women
- Adultery
- Sacrifice of 'seed' to Moloch
- Male homosexuality
- Bestiality of male and female.

One salient feature of all of these biblical laws is that the juridical texts are addressed exclusively to *males*: males are subjects of the incest prohibitions and, for the most part, females are objects. That is to say, specific blood-kindred and marriage-kindred females are cited as forbidden to the relevant *males*.

There seems to be a correspondence between the sexual prohibitions and rules about cooking, hunting, or sacrificing. For example, the rule against boiling a kid goat in its mother's milk parallels the prohibition against a male child having intercourse with his mother. Similarly, laws that prevent certain kinds of acts ('taking' a mother bird and her fledglings and then sending away the mother bird) correspond to the prohibitions against a man 'taking' a woman and her mother.

One reason incest rules find their parallel in rules about hunting, cooking, or sacrificing is that food and eating often serve as metaphors for sexual activity, and such metaphors can and do structure human behavior. Thus, in interpreting the prohibition against cooking a kid goat in its mother's milk, it is implied that one shall not put a mother and her son into the same pot, any more than into the same bed. Indeed, there are a number of biblical narratives in which the role of the kid goat serves as a symbolic substitute for a male child.

The Nature of Taboo

The English word *taboo* derives from Tongan *tabu*. It entered the language towards the end of the 18th century. In this context, the word refers generally to forbidden behavior and includes such things as bans on naming dangerous animals, food restrictions, prohibitions on touching or talking to members of high social classes, and injunctions involving aspects of birth, death, and menstruation. Taboo items are avoided because they are thought to be ominous, evil, or somehow offensive to supernatural powers. To violate a taboo automatically causes harm (even death) to the violator and perhaps his or her fellows. However, taboos do not always involve the possibility of physical or metaphysical injury. Old Polynesia also has evidence of the sorts of taboos on bad manners with which readers of this encyclopedia will be more familiar; in other words, social sanctions placed on behavior that is regarded as distasteful, or at least impolite, within a given social context (cf. Allan and Burridge, 2005: Chapter 1). The taboos of contemporary Western society are of this nature. They rest ultimately on traditions of etiquette and are intimately linked with social organization. A taboo word in a language such as modern-day English is avoided, not because of any fear that harm may befall either the speaker or the audience, but because the speaker could lose face by offending the sensibilities of the audience. Some speakers would claim that to utter taboo terms offends their own sensibilities, because of the supposed unpleasantness or ugliness of the taboo terms themselves. In this context, euphemism is the polite thing to do, and dysphemism (or offensive language) is little more than the breaking of a social convention.

Individual societies differ with respect to the degree of tolerance shown towards any sort of taboo-defying behavior. This depends on their values and belief systems at the time. It was not so very long ago that some transgressions against Western taboos were severely punished, by methods such as imprisonment, hanging, or burning at the stake. In Britain up until the end of the 17th century, blasphemy was punishable by burning. There are still people who would take such biblical commandments as Leviticus 24:16 literally: "He that blasphemeth the name of the Lord, he shall surely be put to death, and all the congregation shall certainly stone him." And even though few in this technically advanced and (for many) secular 21st century would admit to the sort of fear and superstition that they associate with the taboos of exotic and unenlightened peoples, there are many in it who carry talismans when they travel, avoid walking beneath ladders, knock on wood, and believe in lucky and unlucky numbers. For some people, talking about a disease is enough to bring on specific symptoms, and medical students are notorious for discovering that they manifest the symptoms of whatever disease they happen to have been studying. Words can also have curative power. Thus, doctors have had to admit that many cited cancer cures have nonrational explanations.

The kinds of topics placed under taboo change over time (*see* **Taboo, Euphemism, and Political Correctness**). Since the 1980s, English speakers have shown a growing apprehensiveness of how to talk to and about others, particularly those perceived to be disadvantaged or oppressed. There has been a gradual establishment of legally recognized sanctions against what could be described as '-IST language.' The new taboos are sexism, racism, ageism, and religionism, so that sexist, racist, ageist, and religionist language is not only contextually dysphemistic, but also legally so. These taboos have now come to replace the relaxing of laws against profanity, blasphemy, and (sexual) obscenity.

The Nature of Taboo

The English word *taboo* derives from Tongan *tabu*. It entered the language towards the end of the 18th century. In this context, the word refers generally to forbidden behavior and includes such things as bans on naming dangerous animals, food restrictions, prohibitions on touching or talking to members of high social classes, and injunctions involving aspects of birth, death, and menstruation. Taboo items are avoided because they are thought to be ominous, evil, or somehow offensive to supernatural powers. To violate a taboo automatically causes harm (even death) to the violator and perhaps his or her fellows. However, taboos do not always involve the possibility of physical or metaphysical injury. Old Polynesia also has evidence of the sorts of taboos on bad manners with which readers of this encyclopedia will be more familiar; in other words, social sanctions placed on behavior that is regarded as distasteful, or at least impolite, within a given social context (cf. Allan and Burridge, 2005: Chapter 1). The taboos of contemporary Western society are of this nature. They rest ultimately on traditions of etiquette and are intimately linked with social organization. A taboo word in a language such as modern-day English is avoided, not because of any fear that harm may befall either the speaker or the audience, but because the speaker could lose face by offending the sensibilities of the audience. Some speakers would claim that to utter taboo terms offends their own sensibilities, because of the supposed unpleasantness or ugliness of the taboo terms themselves. In this context, euphemism is the polite thing to do, and dysphemism (or offensive language) is little more than the breaking of a social convention.

Individual societies differ with respect to the degree of tolerance shown towards any sort of taboo-defying behavior. This depends on their values and belief systems at the time. It was not so very long ago that some transgressions against Western taboos were severely punished, by methods such as imprisonment, hanging, or burning at the stake. In Britain up until the end of the 17th century, blasphemy was punishable by burning. There are still people who would take such biblical commandments as Leviticus 24:16 literally: "He that blasphemeth the name of the Lord, he shall surely be put to death, and all the congregation shall certainly stone him." And even though few in this technically advanced and (for many) secular 21st century would admit to the sort of fear and superstition that they associate with the taboos of exotic and unenlightened peoples, there are many in it who carry talismans when they travel, avoid walking beneath ladders, knock on wood, and believe in lucky and unlucky numbers. For some people, talking about a disease is enough to bring on specific symptoms, and medical students are notorious for discovering that they manifest the symptoms of whatever disease they happen to have been studying. Words can also have curative power. Thus, doctors have had to admit that many cited cancer cures have nonrational explanations.

The kinds of topics placed under taboo change over time (*see* **Taboo, Euphemism, and Political Correctness**). Since the 1980s, English speakers have shown a growing apprehensiveness of how to talk to and about others, particularly those perceived to be disadvantaged or oppressed. There has been a gradual establishment of legally recognized sanctions against what could be described as '-IST language.' The new taboos are sexism, racism, ageism, and religionism, so that sexist, racist, ageist, and religionist language is not only contextually dysphemistic, but also legally so. These taboos have now come to replace the relaxing of laws against profanity, blasphemy, and (sexual) obscenity.

Taboo Words and the 'Naturalist Hypothesis'

Words are symbolic. The correlation between their form and their meaning is largely arbitrary. Shakespeare was right: "That which we call a rose, by any other name would smell as sweet." There is no natural or necessary connection between the shape of the word *rose* and its meaning 'beautiful fragrant flower.' There is, therefore, no *a priori* basis for distinction between the mentionable euphemism and the unmentionable taboo term. It is mysterious why a euphemistic expression like *I'm going to the loo* has fewer unpleasant connotations than its corresponding taboo term *I'm going for a piss*. The difference presumably derives from the 'naturalist hypothesis' (Allan, 1986: Chapter 2.8); in other words – a persistent belief that the form of an expression somehow communicates the essential nature of whatever it denotes; in Sir James Frazer's words: "... the link between a name and the person or thing denominated by it is not a mere arbitrary and ideal association, but a real and substantial bond which unites the two ..." (Frazer, 1911: 318). It is for this reason that taboo terms are often said to be unpleasant or ugly sounding, and why they are described as 'dirty words.' It also explains their ability to "chill the flesh and raise gooseflesh," as Wyld (1920: 387) observed.

Taboo terms are contaminated by the taboo topics to which they refer, and any euphemism will itself become tainted with time. The degree of contamination perceived in the denotatum ranges on a scale that has at one end fear and contempt, and at the other little worse than low social esteem. A simple example is English *undertaker*. The word once meant 'odd-job man' ('someone who undertakes to do things'), and it was recruited as a euphemism for a person taking care of funerals. However, once used in the taboo context of death, it narrowed very rapidly to the taboo sense alone. It has now been replaced by euphemisms such as *mortician,* and more recently *funeral director*. Compare the rapid narrowing of the word *coffin* from 'a box' to 'a box in which a corpse is buried or cremated.' The once euphemistic *toilet* (from French *toile* 'cloth'), as in *going to the toilet*, is now a direct term and may well disappear entirely, as has *necessary house*. It has already been superseded by *bathroom* or *restroom* in American English and *loo* in spoken British and Australian English. Words denoting sexual activity such as *rape, consummation, erection, copulation, intimacy, orgasm, intercourse, climax, ejaculation, erection, interfere with*, and *seduce* were once quite general terms. However, in all cases the sexual sense now dominates and the euphemistic sheen has now faded.

Taboo areas of the lexicon perpetually generate this sort of narrowing and deterioration of meaning. The result is a constant turnover of vocabulary for words denoting taboo concepts. Very few euphemisms that have degraded in this way into taboo terms come back from the abyss, even after they have lost their taboo sense. This promotes an ever-changing chain of vocabulary for words denoting taboo concepts. It is also apparent that the length of this chain can be directly correlated with the severity of the taboo. For example, the vocabulary for bodily effluvia, sex, and tabooed body parts surely manifests significantly more synonymy than one finds anywhere else in the English lexicon. Here we are dealing with literally thousands of euphemisms. English alone is reported to have accumulated more than 1000 terms for 'penis,' 1200 terms for the 'vagina,' 800 for 'copulation,' and over 2000 for 'prostitute'.

Such is the salience of taboo terms that innocent vocabulary may also be affected, simply because of association. *Regina* makes some people feel uncomfortable because of its phonetic similarity to *vagina,* and they avoid it. *Cunny* (or *cony*) 'rabbit' dropped from the lexicon because of the taboo homonym meaning 'cunt.' Gender, sexuality, disability, and especially race are now so highly charged that speakers will shun anything that may be interpreted as discriminatory or pejorative – and this includes blameless bystanders that get in the way. The word *niggardly* has no etymological connections with the taboo term *nigger,* yet many Americans now sidestep the expression. The effects of taboo can also work across languages. In the Nootka Indian language of Vancouver Island, British Columbia, the English word *such* so closely resembles the Nootka word meaning 'cunt' that teachers find it very difficult to convince their students to utter the English word in class. Similar reports of crosslanguage effects have been reported elsewhere.

The Case of Naming Taboo

'To say a tabooed name is to assault the owner of the name, and requires sanctions to be brought against the offender. Punishment for violation of a taboo can be in the form of religious propitiation of an offended spirit, payment of goods to an offended party, or exchange of goods to restore harmony between the guilty and the injured. Breaking the taboo can lead to death by murder, or suicide due to shame' (Holzknecht, 1988: 45).

Throughout history, people have attributed supernatural powers to names, and naming forms a special case of word taboo. One of the fears about names is their magical power, hinted at in proverbs like *speak*

of the devil and he comes running, and in the avoidance of names for diseases, dangerous things and animals, gods, and powerful men.

Personal names (that is, 'true names') are taboo among peoples in many parts of the world. This is also a fear-based taboo. Sorcerers and enemies can harm a person whose true name they know; knowledge is power. A name is regarded as an inalienable part of the name bearer, not just a symbol but the verbal expression of his or her personality. Other properties of personal representation such as mind, spirit, soul, shadow, and reflection are often treated in the same way (cf., Chappell and McGregor, 1996). This can have repercussions for the grammar as illustrated in the following example from Pitjantjatjara (Central Australia):

(1) ngayu-nya ini
1.sing-ACC name
'my name'

(2) ngayu-nya mara
1.sing-ACC hand
'my hand'

(3) ngayu-ku karli
1.sing-POSS boomerang
'my boomerang'

Because 'true' names are so closely associated with their name-bearer as to be a proper part of him or her, in some societies (for example, traditional Austronesia) there are strict taboos preventing two living persons from going by the same name. Furthermore 'true' names are often secret, rendering euphemistic names necessary for public naming and addressing. For English, such taboos are observed only for *God* or *Christ,* and then only inconsistently.

When Name Taboo Extends into Word Taboo

In many societies, names of the dead are (or were until recently) taboo. Sometimes the ban extends to those personal names which the dead person may have given to others. Violations of such taboos are believed to cause misfortune, sickness, and death; they may also cause offense to living descendants. Although native English-speaking communities do not have such fearsome taboos, there are many euphemisms for the topic of death and the dead.

Naming taboo can have far-reaching consequences when names are or derive from common words. Simons (1982) described how in a sample of 50 Austronesian languages known to have some sort of naming taboo, 25 of these involve common word taboo. In a further 18, words resembling tabooed names are themselves subject to taboo. For example, if the tabooed name is *Ikio,* then the word *kio* 'bird' is tabooed. The effect of this is that on the island of Malaita as much as 59% of the everyday vocabulary is taboo for some people. Euphemisms are thus created via semantic shifts of existing words, circumlocution, borrowing from another language, and phonological modification (*see* **Taboo, Euphemism, and Political Correctness**). Sounds can turn up in unexpected places, and they mutate unexpectedly. The situation can be compared to the change in English from *shit* to *shivers* or *fuck* to *fudge*. Because the lexicons of these languages are so unstable, it is often difficult to determine the chronology of linguistic changes that have occurred. Even genetic connections between languages can be obscured.

Aboriginal Australia provides another example of the effects of naming taboo on vocabulary. In many traditional Australian Aboriginal communities, any kind of vocabulary item, including grammatical words, can be proscribed if it is phonetically similar to the name of a dead person. Replacement vocabulary is created using synonyms from the language's own repertoire (or from an auxiliary repertoire of 'respect language'), semantic shifts of existing words, compounding, circumlocution, borrowing from a neighboring language, and in some cases a hand sign or gesture. Some languages have special vocabulary items to be used in place of proscribed words, sometimes a kind of 'whatsitsname' / 'whatchamacallit' word or one that is reserved especially for the purpose of name-avoidance.

A striking illustration involves the changes to the first person pronoun in some dialects of the Western Desert. On the death of a man named *Ngayunya,* these languages replaced the pronoun *ngayu* 'I/me' with *nganku*. Subsequently this term was itself tabooed and replaced by either English *mi* or by *ngayu* borrowed back into the language from dialects where it had never been tabooed (cf., Dixon, 1980: 29). This shows that the taboo on a word may cease after some years have passed, allowing it to come back into use. This recycling is one of the very few ways in which a tabooed item can itself become a euphemism. Indeed, Alpher and Nash (1999) claimed that, where we are in a position to check the history, such cases of tabooing have always proved to be temporary. The taboo on a word may cease after some months, or one or two years, have passed, allowing the word to come back into use. Moreover, it appears that there is no absolute prohibition on mentioning the name of a dead person. Vocabulary is taboo for only those people who stand in a certain relationship with the deceased. Locals can continue to use the taboo forms out of earshot of the bereaved family.

As earlier described, taboos and attitudes towards taboo violation do change over time. Societies like those of Aboriginal Australia and Austronesia are not closed to innovation and are certainly not closed to importing cultural elements from outside. Many of these old taboos have been affected by the spread of Western ideas and are now disappearing.

Euphemism and Taboo

Examples of euphemism (Greek *eu* 'good, well' and *phêmê* 'speaking') are wide ranging: medieval Dutch physicians used to write of *figs in the secret passage* to denote 'piles'; 19th-century Victorian moral code created 'invisible' words like *inexpressibles, unmentionables,* and *unhintables* so that those in polite society could avoid uttering *legs*, *trousers,* or *underclothing*; some people still say *crumbs* instead of *Christ*; many newspapers still print *c**** and *f****; politicians speak of *community charges*, *levies,* or even *voluntary contributions* rather than of *taxes* or *tolls*; *prairie oysters, mountain oysters*, and *fry* sound more appetizing than *calf's testicles*; *lemon fish* and *flake* far tastier than *shark*; companies *downsize*, *rightsize*, or implement an *RIF* (= reduction in force); 1998 was the 'Year of the Older Person' (not 'The Year of the Old Person'); the push for nonsexist usage has rendered words like *stewardess* and *actress* taboo for some people, and so on.

As these few examples illustrate, euphemism is characterized by avoidance language and evasive expression. In contemporary Western society it is linked closely with social organization and is therefore entwined with concepts of politeness and face. Generally social interaction is oriented toward behavior that is courteous and respectful, or at least inoffensive. Participants have to consider whether what they are saying will maintain, enhance, or damage their own face, as well as be considerate of and look after the face needs of others. Hence, we can define a euphemism as follows:

> A euphemism is used as an alternative to a dispreferred expression, in order to avoid possible loss of face: either one's own face, or though giving offense, that of the audience, or of some third party. (Allan and Burridge, 1991: 11)

What is described here as 'a dispreferred expression' is one that is not desired or appropriate on a given occasion. Typically it denotes a taboo topic and so might alternatively be called 'a taboo term'. A speaker (or writer) uses a euphemism to escape disapproval and to avoid offending the hearer (or reader) or even some third party (an eavesdropper or bystander). Some speakers would also claim that the obnoxious nature of taboo terms is offensive to their own sensibilities.

In its original conception, as borrowed from Tonga, the word *taboo* (or *tabu*) refers to forbidden behavior, in particular, behavior believed to be dangerous to certain individuals or to the society as a whole. In this context violations of taboos are expected to have dire consequences and euphemism can be literally a matter of life or death (*see* **Taboo Words**).

As earlier described, taboos and attitudes towards taboo violation do change over time. Societies like those of Aboriginal Australia and Austronesia are not closed to innovation and are certainly not closed to importing cultural elements from outside. Many of these old taboos have been affected by the spread of Western ideas and are now disappearing.

Euphemism and Taboo

Examples of euphemism (Greek *eu* 'good, well' and *phêmê* 'speaking') are wide ranging: medieval Dutch physicians used to write of *figs in the secret passage* to denote 'piles'; 19th-century Victorian moral code created 'invisible' words like *inexpressibles, unmentionables,* and *unhintables* so that those in polite society could avoid uttering *legs*, *trousers,* or *underclothing*; some people still say *crumbs* instead of *Christ*; many newspapers still print *c**** and *f****; politicians speak of *community charges*, *levies,* or even *voluntary contributions* rather than of *taxes* or *tolls*; *prairie oysters, mountain oysters*, and *fry* sound more appetizing than *calf's testicles*; *lemon fish* and *flake* far tastier than *shark*; companies *downsize*, *rightsize*, or implement an *RIF* (= reduction in force); 1998 was the 'Year of the Older Person' (not 'The Year of the Old Person'); the push for nonsexist usage has rendered words like *stewardess* and *actress* taboo for some people, and so on.

As these few examples illustrate, euphemism is characterized by avoidance language and evasive expression. In contemporary Western society it is linked closely with social organization and is therefore entwined with concepts of politeness and face. Generally social interaction is oriented toward behavior that is courteous and respectful, or at least inoffensive. Participants have to consider whether what they are saying will maintain, enhance, or damage their own face, as well as be considerate of and look after the face needs of others. Hence, we can define a euphemism as follows:

> A euphemism is used as an alternative to a dispreferred expression, in order to avoid possible loss of face: either one's own face, or though giving offense, that of the audience, or of some third party. (Allan and Burridge, 1991: 11)

What is described here as 'a dispreferred expression' is one that is not desired or appropriate on a given occasion. Typically it denotes a taboo topic and so might alternatively be called 'a taboo term'. A speaker (or writer) uses a euphemism to escape disapproval and to avoid offending the hearer (or reader) or even some third party (an eavesdropper or bystander). Some speakers would also claim that the obnoxious nature of taboo terms is offensive to their own sensibilities.

In its original conception, as borrowed from Tonga, the word *taboo* (or *tabu*) refers to forbidden behavior, in particular, behavior believed to be dangerous to certain individuals or to the society as a whole. In this context violations of taboos are expected to have dire consequences and euphemism can be literally a matter of life or death (*see* **Taboo Words**).

Taboos Western-style, however, are selective. Typically they rest on traditions of etiquette and are therefore set by social parameters such as age, sex, education, social status, and the like. The taboo topics English speakers are most familiar with are avoided because they are felt to be embarrassing or offensive under certain social circumstances. Whether you *micturate, powder your nose, go to the washroom, take a leak, a piss,* or *a pee*, the choice is a matter of appropriate style. Such taboos may be observed in private, but they are their strongest in the public domain. In this context euphemism is matter of good manners.

Not all euphemisms arise in response to taboo, however. In their ability to place whatever it is they designate in a favorable light, many are simply alternatives for expressions speakers prefer not to use on a given occasion. For example, Clause 28 of the Melbourne Metropolitan Planning Scheme has several references to the *accommodation of stationary vehicles*. For the document's author this phrase presumably has more positive connotations, or at least fewer negative connotations, than either *parking places* or *car spaces*. Such euphemisms are positive expressions that are used to enhance the denotatum (in other words, what is being referred to), perhaps even to amuse. There are often no real taboo counterparts – *potholes* are simply upgraded to *pavement deficiencies*, *dried beans* to *Alaskan strawberries*.

Types of Euphemism

The following offers a brief classification and examples of the main sources of euphemism. All involve some kind of verbal disguise. They are by no means mutually exclusive, however, and many fall into more than one category; for instance, euphemistic expressions such as *at the evening of one's days, the autumn* or *the winter of one's life* for 'old' are both metaphorical and long-winded.

Shortening

Many euphemisms are made by shortening a word. There are a number of different processes:

- Clippings like *jeeze* and *gee* for 'Jesus', *bra* for 'brassiere' (both end-clipped), and the archaic *nation* for 'damnation' (this is fore-clipped)
- Acronyms like *snafu* for 'situation normal, all fucked up'
- Abbreviations like *S.O.B.* for 'son-of-a-bitch' or *pee* for 'piss'. Also *f –* and *s –* instead of 'fuck' and 'shit'
- Omissions like *There's the pot calling the kettle black* where *arse* is missing from the end; also *I need to go,* which omits *to the lavatory,* and *past it,* which omits something like 'one's prime'. Some omissions substitute nonlexical expressions (dashes, asterisks) for the dispreferred term; for example, Grose's dictionary (1811) uses four asterisks as a synonym for the 'vagina'. The spoken counterparts to dashes and asterisks are noises like *mhm, er-mm*.

Circumlocution

Long-winded expression can be effective linguistic camouflage. Often it involves a type of componential analysis, whereby the senses of taboo terms are unpacked and each of the meaning components are listed. The resulting periphrasis functions as a euphemism, such as *postconsumer secondary material* for 'garbage', *excrementitious human kidney fluid* for 'urine', and *solid human waste* for 'faeces'.

Remodeling

The sound of words can be changed to disguise something that is offensive. This can involve various processes (of largely verbal play):

- Phonological distortion, whereby speakers intentionally distort the pronunciation of words; for example, expressions for 'Christ' such as *cripes, crust, crumbs, crikey*; also *heck* from 'hell' and *shite* from 'shit'
- Blending involving portmanteau words such as *strewth* from 'God's truth', *zounds* from 'God's wounds', and *drat* from 'God rot'
- Reduplication whereby syllables or letters of words are repeated; for example, *jeepers creepers* for 'Jesus Christ', *twiddle-diddles* 'testicles', *tuzzy muzzy* 'vagina', and *rantum-scantum* 'copulate'
- Alliteration and rhyming (slang) such as *om-tiddly-om-pom* and *umpti-poo* for 'toilet', *jimmie-riddle* 'piddle, piss', *bristols [Bristol cities]* 'titties/breasts', and *Brahms [and Liszt]* 'pissed, drunk.'

Semantic Change

A number of semantic processes can be used to create new euphemisms:

- Metaphor involves the pairing up of a taboo topic with another (usually pleasurable) notion. Sometimes chains of figurativeness are established; for example, euphemisms to do with 'old age' include *riper years* (or at a *ripe old age*), *mellow*, *mature*, *the golden years* (and *the golden agers*), *sunset years*, *twilight years,* and so on.
- General-for-specific is a common (metonymic) strategy whereby taboo items are substituted by

very general or abstract words; for example, euphemisms like *nether regions*, *chest*, *loin,* and *groin* shift focus to the general area where unmentionable body parts are roughly situated.

- Elevation involves the substitution of words with more pleasing connotations. For example, *crafted* implies that something has been produced meticulously and probably by hand and is more positive than *made* or *manufactured*, *blend* is more positive than *mixture*, *standard* more positive than *average*.

External Borrowing

Using words borrowed from other languages to function as euphemisms is characteristic of many languages. French and Latin provide English with many of its euphemisms for bodily effluvia, sex, and the associated acts and bodily organs; for example, *perspire* instead of *sweat*, *expectorate* instead of *spit*, *defecate* and *faeces* instead of *shit*.

Internal Borrowing

Euphemisms can also be borrowed from different sublanguages. Technical jargon provides euphemisms such as *treponemal disease, luetic disease, spirachoetal disease* for 'syphilis'. The antithetical strategy is the use of slang items like *cupid's measles* for 'syphilis'.

Dysphemism and Orthophemism

Whereas the term *euphemism* is well known and has wide currency, dysphemism (Greek *dys* 'bad, unfavorable' and *phêmê* 'speaking') rarely appears in ordinary language. It is, roughly speaking, the counterpart of euphemism and can be defined as follows:

> A dysphemism is a word or phrase with connotations that are offensive either about the denotatum and/or to people addressed or overhearing the utterance. (Allan and Burridge, in press: Chapter 2)

Dysphemism involves the verbal resources for being offensive, being abusive, or just plain letting off steam. Like euphemism, it is motivated by fear and distate, but also by hatred and contempt. Speakers resort to this type of expression to talk about people and things that frustrate and annoy them and that they disapprove of and wish to humiliate or degrade. Dysphemistic expressions therefore involve curses, name-calling and any sort of derogatory comment directed toward others to insult or wound them. They also include exclamatory swearwords; in other words, expletives used to release frustration or anger. Like euphemism, dysphemism interacts with style and has the potential to produce stylistic discord; for example, if someone at a formal dinner party were to publicly announce '*I'm off for a piss*,' rather than saying something like '*excuse me for a moment*'.

Dysphemism employs most of the same strategies as euphemism, but there is one main difference. Whereas (vague) general-for-specific euphemisms are commonplace, dysphemism is more likely to employ a (blunt) part-for-whole strategy; for example, *tits* for 'breasts' (versus euphemistic *chest*) or figurative epithets like *he's a prick* (versus the legalistic euphemism *person* for 'penis'). Other differences are predictable. The use of borrowed terms, circumlocution, or technical jargon is usually dysphemistic when it is perceived by the audience to be befuddling gobbledygook.

The concepts of euphemism and dysphemism imply the presence of direct terms that are neither sweet-sounding, evasive, overly polite (euphemistic) nor harsh, blunt, offensive (dysphemistic). Such expressions might be described as orthophemisms (Greek *ortho* 'proper, straight, normal' and *phêmê* 'speaking'). As alternatives to offensive expressions, orthophemisms, like euphemisms, will typically be preferred; in other words, desired or appropriate terms. An example of all three language expressions would be *pass away* (the euphemism), *croak* (the dysphemism), and *die* (the orthophemism). However, these descriptions are problematic because what determines them is a set of social attitudes or conventions that may vary considerably between dialect groups and even between individual members of the same community. Given there is such complexity and variety of opinions and attitudes, we are unlikely to ever find uniformity of judgment between speakers of even very similar social backgrounds. There can be no such thing as 'Everyman's euphemism' or 'Everyman's dysphemism'. X-phemisms (the union set of euphemisms, orthophemisms, and dysphemisms) are primarily determined from evaluating an expression within the particular context in which is it uttered. For example, the term *die* is direct and in some contexts might well be the neutral and mundane orthophemism. However, in another more personal context it might also conjure up an image that some people would find just too vivid. On that occasion it would be offensive, or dysphemistic. On the other hand, a blunt expression like *croak* can also be euphemistic between certain individuals. Its flippancy detracts from the seriousness of death, which makes it preferable to a more direct term like *die*. A jocular approach to death is offensive only if it can be expected that the hearer would regard it as such.

Even though the choice between alternative expressions will always depend on context, ordinary people do perceive expressions to be somehow intrinsically X-phemistic. For example, terms for *die* such as *pass*

away and *sleep* are euphemistic, whereas *croak* and *peg out* are not. In the British survey Millwood-Hargrave (2000), participants were asked to respond to the perceived 'strength' of 28 swearwords. No context was provided. Yet, participants were clear about the severity of these words, and the researchers were able to put together a broad topography of swearwords across all groups. Modern dictionaries also treat expressions as if they were intrinsically dysphemistic when they indicate offensive connotations of particular entries. The *Encarta World English Dictionary*, for example, recognizes three degrees of offensiveness: insulting, offensive, and taboo. Out of context this sort of 'sensitive handling' employs a type of good etiquette gauge by which is determined the X-phemistic value of an expression without reference to the context of use. Those who compile dictionaries of euphemisms and dysphemisms (like Ayto, 1993; Green, 1996) also base their collections on the prejudiced social attitudes to the situation in which they believe a given expression is uttered. What is envisaged is something like a 'middle-class politeness criterion': in order to be polite to a casual acquaintance of the opposite sex in a formal situation in a middle-class environment, a speaker would normally be expected to use a euphemism or orthophemism rather than the dispreferred counterpart, or dysphemism (cf. Allan and Burridge, in press: Chapter 2). This is the criterion that is automatically assumed in the public domain, for example in writing, where the exact composition of one's audience is not likely to be known. Etiquette demands that in this context language be chosen carefully and consciously with a respectable (and probably mixed) middle-class audience in mind.

Changing Taboos

> . . . if you were driving in your car, somebody cuts you up in your car, if they shout and call you a f-ing idiot, or a bloody idiot or whatever, fair enough. If they start putting your racial background into that, it's unacceptable. [Interview Black British family, North London, Millwood-Hargrave, 2000: 20]

In English-speaking societies profanity and blasphemy still provide the basis for fairly potent dysphemistic expressions, though with the increasing secularization of these communities clearly not as potent as they once were. However, as some taboos relax others come to replace them. English now has many expletives, insults, and abusive epithets that name bodily emissions, tabooed body parts, and sexual pastimes. Moreover, contemporary English-speaking societies have evolved new taboos to do with gender, sexuality, disability, and especially race and ethnicity. These topics are now so extremely charged, they have sparked many different forms of avoidance behavior. There is a new apprehensiveness and shunning of anything, especially established vocabulary, that may be interpreted as discriminatory or pejorative. The push for equality and equal opportunity has given rise to legally enforceable fairness, sensitivity, and tolerance, and sanctions against what might be dubbed *-ist* language (such as sexist, racist, ageist, religionist language) have come to replace relaxing laws against profanity, blasphemy, and (sexual) obscenity.

The British report Millwood-Hargrave (2000) mentioned earlier provides qualitative and quantitative evidence for the linguistic fallout from these new taboos. Research carried out jointly by the Advertising Standard Authority, the British Broadcasting Corporation, the Broadcasting Standards Commission, and the Independent Television Commission tested people's attitudes to swearing and offensive language. The results revealed that the least-offensive were words involving verbal play such as 'baby talk' (*poo* and *bum*) and rhyming slang (*berk*). Ranked slightly higher were the profanities (*God, Jesus Christ*) followed by expressions relating to sexual and bodily functions (expletives such as *shit* and *fucking hell* and sexual references such as *shag* and *pussy*). At the top of the scale of severity was derogatory language toward minority groups, including people with disabilities, those from different religious faiths, homosexual men and women, ethnic minorities – 'most severe' of all was racial abuse.

The evolving nature of taboo is reflected in changes to dictionary-making conventions. Dictionaries originally included religious and racial swearwords and omitted sexually obscene words, but the last century saw mounting pressure on editors to alter, or even omit altogether, political and racial definitions of words. Robert Burchfield (1989) recounted the fierce debates in the early 1970s over the decision by the *Oxford English Dictionary* to include the opprobrious senses of the word *Jew*. Lakoff (2000: 39–40) discussed a dispute between the publishers of the *Merriam-Webster's Collegiate Dictionary* (10th edition) and members of the African American community over the definition of *nigger*. The dictionary had indicated the offensive connotations of term but only after the initial neutral definition of *nigger* as 'black person'. Those disputing the definition wanted the word listed primarily as a 'slur' with the derogatory sense part of the principle denotation. When the *Encarta World English Dictionary* first appeared in 1999, it was described by reviewers as 'extremely sensitive to political correctness' (David Isaacson, 1999, Radio WMUK, 102.1 FM) and 'PC in the extreme' (Quinion, 1999).

Equally revealing of changing taboos is the behavior of the self-appointed guardians of the language such as Dr. Thomas Bowdler. In the early 19th century, he and his sister set out to expurgate Shakespeare. They produced the 'Family Shakespeare' from which, as was announced on the title page, "those words and expressions are omitted which cannot with propriety be read aloud in a family" (cf. Hughes, 1991: Ch. 11). Bowdlerism, as it came to be known, targeted profanity and sexual explicitness and led to the progressive sanitizing of a range of works. Allan and Burridge (forthcoming) described a more recent case of bowdlerism by the New York State Education Department whereby the English literary texts for the Regents exam were cleansed of any references to race, religion, ethnicity, sex, nudity, alcohol, and profanity. The targets of the modern-day bowdlerites are different, but the cleaning-up activities remain the same – only the definition of 'dirt' has shifted.

Political Correctness and X-Phemism

Although modern dictionaries of euphemism (such as Ayto, 1993) include politically correct (or PC) expressions among their entries, many accounts of nondiscriminatory language in handbooks such as Banks and Mulder (1996) expressly deny the language they are recommending is euphemistic. The reasons they offer are twofold.

For one, there is the view that politically correct usage calls for a more precise and accurate use of language. The argument goes: because women can also chair meetings, *chairperson* is not euphemistic, it is simply accurate. Moreover, many handbooks add that political correctness is also a straightforward matter of calling groups by the names they prefer. The terms *married* and *de facto spouse* only include those relationships that can be sanctioned by legal or quasi-legal marriage; in other words, heterosexual relationships. A term such as *partner* sidesteps that issue and is therefore more representative. The term *queer* is preferred by many because it is seen to include groups such as bisexuals and transsexuals, which *gay* and *lesbian* do not.

Secondly, there is the view that politically correct language is a form of public action. By drawing attention to form, it forces us to sit up and take notice. The use of 'generic' *she*, for example, can be intentionally distracting. Or the use of *he/she* and *him/her* is intended, by some at least, to be deliberately clumsy. As Dwight Bolinger put it (although not in a PC context), the double pronoun 'refuses to take the back seat that all languages serve for pure anaphora' (1980: 96). Moreover, politically correct terms also deliberately highlight certain aspects of these particular groups' identity. When members of the Black community campaigned for *African American,* it was to emphasize not genetics or color, but the historical roots of a group that now forms part of the United States, thus bringing the name into line with those of other ethnic minorities such as Japanese American and Italian American groups.

These accounts of PC-motivated language change fall well within the realm of euphemism. The use of inappropriate styles for naming and addressing is dysphemistic and likely to affront the hearer's face; appropriate naming and addressing is polite and therefore euphemistic. If political correctness has to do with extending to others the common courtesy of naming them as they would prefer to be named, then this is straightforwardly euphemistic (or at least orthophemistic) behavior. But there is also more to euphemism than simple politeness. Certainly euphemisms are motivated by the desire not to be offensive, and so they have positive connotations; at the least they seek to avoid too many negative connotations. But euphemisms are often more than 'linguistic fig-leaves'. Many euphemisms for death, for example, do more than just cover up abhorrent reality. They emphasize different aspects of the physical event of death and dying; for example, death as a journey (*pass away*) or death as the beginning of new life (*go to a better place*). The image they offer is then one of consolation. Furthermore, in the mouth or pen of a political satirist, euphemisms are often deliberately provoking. A political allegory such as Jonathan Swift's *Gulliver's Travels* is at one level a children's story and at another one of the most blistering satires of the human condition ever written (cf. Allan and Burridge, 1991: Ch. 10). Similarly, PC-inspired euphemism aims not to disguise or conceal unpleasant reality, but to compel its audience to go beyond the simple content of the message and to challenge assumptions that some assume are in-built and immutable aspects of their language.

The reluctance of writers to view PC language as part of euphemistic behavior stems from the deterioration of the term *euphemism* itself. For many people 'euphemism' is now the pejorative label they attach to language they believe to be value laden and deliberately obfuscating. They associate it with unwanted jargon that they suspect is used primarily to befuddle and disguise ordinary and inconvenient facts. It really is very much an Orwellian-inspired view of euphemism that has come to dominate public discussion. Part of this Newspeak image is the notion that all euphemism is deodorant language used primarily to cover over unpleasant realities. In this way it has become a double-edged sword, used by *both* supporters and critics of PC language to back their respective

positions. In their nondiscriminatory language handbook, Banks and Mulder (1996: 34) state that "responding to others with care and sensitivity involves describing people accurately, from an informed position. Euphemisms, or unnecessarily vague terms patronise people". In the other camp, critics of political correctness, impatient with what they see as a pretense that sweeter words produce a sweeter world, scorn political correctness precisely because they argue it *is* just euphemism; for example, Robert Hughes's (1993: 18–19) famous description of PC language is as a kind of "linguistic Lourdes, where evil and misfortune are dispelled by a dip in the waters of euphemism".

Because the choice between alternative expressions will always depend on context, politically correct language will inevitably be both euphemistic and dysphemistic, more strikingly so because of its overtly political nature. *Deaf* is preferable to *hearing-impaired* for those who identify with *Deaf Pride*. Some women feel affronted and wrongfully excluded by compounds like *chairman*; others are quite happy to remain *Madam Chair* because they understand *chairman* to be an idiom denoting the office of chairperson. Australian Aborigines reportedly show no strong aversion to using terms such as *blackfella, Abo,* and *boong* among themselves (Eagleson *et al*., 1982: 157). In certain contexts, African Americans can call one another *nigger* with impunity (Lakoff, 2000: 105). In the mouths of outsiders these terms remain highly offensive, but not in the mouths of those speakers with 'natural cover'; in other words, those who because of their group identity are not presumed to have malign motives for expressing themselves in a potentially offensive way (Loury, 1993: 615). In this way it is possible to reclaim pejorative language; for example, the successful reevaluation by certain groups of the derogatory semantics of words such as *wog* 'Caucasian Australian who is not Anglo-Celtic' as evident in the success in Australia of movies like *Wogs out of Work* and *Wog Boys*. Other examples of reclaimed vocabulary include *bitch, nigger,* and *queer.*

X-Phemism and Language Change

Sociology has Knight's Law: 'Bad talk drives out good'. Economics has Gresham's Law: 'Bad money drives out good'. Linguistics has a similar Law of Semantic Change: 'Bad connotations drive out good' (*see* **Connotation; Taboo Words**). Euphemisms frequently degenerate into dysphemisms through contamination by the taboo topic. If society's prejudiced perceptions continue to bubble away, eventually the euphemistic value will be undermined, and the negative connotations will reattach themselves, and a new euphemism must be found.

For example, such is the stigma surrounding mental illness that any euphemism for the condition will quickly degenerate into dysphemism. This gives rise to a type of lexical treadmill effect. The word *insanity* derives from Latin *in-* 'not' + *sanus* 'healthy'. Now confined to 'mentally unsound', it originally had a much broader domain encompassing all bodily organs and their functions. Today even the word *sane* has narrowed under the influence of *insane* to designate a mental condition only. *Crazy* was once applicable to all manner of illness, but is now also restricted to mental illness alone. The history of the word *deranged* illustrates a typical path of development for euphemisms. Originally from a verb meaning 'to disturb, disarrange', it could be qualified with the modifier *mentally* to refer to people who were 'disturbed in the mind'. But once used in the context of mental illness, the word soon became contaminated and now without the modifier has narrowed to the 'mad' sense alone. The adjective *mental* has also been affected. Dictionaries still list 'pertaining to the mind' as its central sense, but 'denoting a disorder of the mind' is always given as a secondary meaning, as are colloquial senses 'mad' and 'foolish' (compare *be/go mental*, and *become a mental patient*). There are signs that *disordered* and *afflicted* are moving in the same direction. Though still requiring a modifier like *mentally* to refer specifically to psychiatric illness, this is now becoming their normal context of use. And although dictionaries define *sick* as 'affected by any disorder of health', in slang usage the word has narrowed to 'mental ill health', frequently with overtones of 'perversion' (compare *sicko* and *sicknik*).

The names for establishments holding mental patients are subject to the same pejoration and narrowing of meaning. A striking illustration is *asylum*. In Latin the word meant 'place of refuge, retreat', a sense still retained in *political asylum*. At first it appears to have been used of an institution for debtors and criminals; but was later broadened to include the orphaned, the blind, the deaf, and also the mad – when it required some sort of qualifier such as *lunatic*. These days the ordinary understanding of *asylum*, at least in reference to a building, is now specifically 'institution for the care of the insane'.

Political Correctness and Self-Censorship

PC language is politically motivated, and that means it will attract more attention and more resistance than most euphemisms – terms (both PC and non-PC) are politically loaded. It is also euphemism that is

perceived to arise directly out of linguistic intervention. Speakers dislike linguistic change, especially if it smacks of deliberate manipulation. Moreover, PC-motivated name changes are viewed by many as 'the thin end of the wedge' that will work to fragment society into different factions and special-interest groups. This hostility is further fueled by the media hyperbole and misrepresentation that has accompanied the PC debate. Yet, political correctness has been very effective in getting people to alter their language habits, far more effective than other kinds of prescriptive practices. Generic *he* (as in *if a student wants to, he can collect the readings early*) and terms such as *chairman, man-made, lady doctor, woman priest,* and *authoress* are rarely encountered these days.

It is difficult to assess the degree to which the changes are the direct consequence of recommendations made by handbooks and style guides (cf. Pauwels, 1993: 115 on the implementation of non-sexist language planning). These are only ever guidelines and rely on people's own personal decisions to alter their language. And although there have been formal speech codes imposed on some U.S. campuses and other kinds of official prohibitions making it an offense to use expressions deemed sexist, racist, homophobic, or anti-Semitic, these sorts of legal restrictions are by no means commonplace and speech codes are difficult to enforce anyway (Lakoff, 2000: 111).

Societal shifts will always have linguistic repercussions, especially for the lexicon, and PC-driven changes are therefore partly a form of natural linguistic evolution in the face of more general social change. But specifically the issue here is one of the voluntary limitation on speech. As Loury (1993) described it, political correctness has created a climate of tacit censorship. One of the reasons for people's hostility toward political correctness is that a violation of PC protocol can become an inquiry into their character. When people without 'natural cover' express themselves in an 'incorrect' way, there is always the danger that their audience will judge them on what is known about the character of others who have spoken in a similar way, and this can mean true racists, true homophobes, true misogynists, whose motives *are* malevolent. People are always mindful of what an expression might 'sound' like. They will not risk being misunderstood. If advocates of diversity insist that Australian Aborigines be referred to as Koories, then the safest thing is to adopt the PC-approved terminology. Of course if the group itself want this label, then this also becomes a matter of simple civility. (However, this is never a straightforward matter. The term "Koori" is a controversial one, and not all Aboriginal groups wish to go by that name. Political correctness battles are often as much about who has the power to name as the naming itself – who decides the identity of a group and its wants and interests.)

This behavior is no different from the sort of conscious or unconscious self-censoring speakers engage in generally, especially where taboo is involved. Most significant here is the relative saliency of taboo terms. Any derogatory or unfavorable denotation or connotation within language expressions will dominate the interpretation of their immediate context (see Osgood *et al.*, 1957; MacWhinney *et al.*, 1982; Allan and Burridge, 1991: 21–24; *see also* **Connotation; Taboo Words**). One reason that speakers are always quick to drop the homonyms of taboo terms is that they simply won't risk appearing to use a taboo term when none was intended. For example, those in polite society in the 19th century were so fearful of any seeming impropriety that they avoided the terms *leg* and *breast*, even when speaking of a cooked fowl, referring instead to its *dark meat* and *white meat*. In the case of a failure to follow a PC regime there is more at stake, as evident in the now shocking nature of those flippant references to *niggers* and *chinks* that were once second nature to writers like Rudyard Kipling. Use non-PC terms now and doubts are raised about your basic moral commitments – the safest course to steer is clearly one that carries the PC stamp of approval.

Final Remarks

For reasons of fear and or distaste, all human groups have taboos of one kind or another on certain diseases and aspects of death. For the same reasons, all experience anxieties over those body parts, bodily functions, acts, and actions that answer to the 'call of nature'. Verbal taboos, even those imposed by purely social conventions, serve direct human interests by avoiding the things that threaten to cause distress and offense. Taboos exist to strengthen social cohesion. Private dysphemism in the form of swearing might relieve the frustration and distress of the swearer, but other forms of dysphemism make for discord. In the case of avoidance speech styles such as the 'mother-in-law' languages once used extensively in Aboriginal Australia, conflict is prevented where relationships are sensitive and threaten to disorganize the family unit. Relationships with in-laws are notoriously difficult in all societies, and these 'mother-in-law' languages and similar taboos on naming and addressing are grounded in the desire to maintain social harmony in what human communities recognize to be the most difficult area of intrahuman relationships. In today's vastly diverse democratic societies the practical problems of maintaining

dialogue means attention to face-saving is now more critical than ever, if our heterogeneous societies are to be able to negotiate their way through the tensions and differences.

Euphemism provides the verbal escape hatch for speakers confronting the problem of how to talk in different contexts about things that might embarrass them, frighten them, or that are for some reason just plain difficult. These include body parts, bodily functions, sex, lust, anger, notions of social status, hate, dishonesty, drunkenness, madness, disease, death, dangerous animals, fear, God, the supernatural – and since the 1990s, the problem of how to talk to and about others, particularly others perceived to be disadvantaged or oppressed. There will always be cross-cultural and historical differences, but they are superficial. Underlying motivations remain the same. All euphemisms (and dysphemisms) communicate an attitude both to the hearer and also to what is spoken about. In politically sensitive taboo areas, where words can transform into creedal cudgels, there is much more at stake. PC language communicates a political attitude, and that is what makes its expression so volatile.

Taboo: Verbal Practices

F Merlan, Australian National University, Canberra, Australia

© 2006 Elsevier Ltd. All rights reserved.

'Verbal taboo' might be broadly conceived to comprehend a spectrum of linguistic practices ranging from euphemism, the deliberate 'softening' (Cameron, 1995: 73) through lexical substitution or other means of negative associations of words that deal with prohibited or stigmatized subjects, to more systematically structured replacement of normal forms that relate to such subjects as defined within particular speech communities, with other forms understood to specially index, and thus draw attention to, those very subjects and tokens of their occurrence. Despite the wide range of phenomena that might fall under this rubric, the designation '(verbal) taboo' has tended to be used mainly with reference to practices in which suppression and replacement of forms is extensive, highly systematized with reference to definable contexts of occurrence (normally both presupposed and configured by the usage), and accompanied by heightened consciousness and

dialogue means attention to face-saving is now more critical than ever, if our heterogeneous societies are to be able to negotiate their way through the tensions and differences.

Euphemism provides the verbal escape hatch for speakers confronting the problem of how to talk in different contexts about things that might embarrass them, frighten them, or that are for some reason just plain difficult. These include body parts, bodily functions, sex, lust, anger, notions of social status, hate, dishonesty, drunkenness, madness, disease, death, dangerous animals, fear, God, the supernatural – and since the 1990s, the problem of how to talk to and about others, particularly others perceived to be disadvantaged or oppressed. There will always be cross-cultural and historical differences, but they are superficial. Underlying motivations remain the same. All euphemisms (and dysphemisms) communicate an attitude both to the hearer and also to what is spoken about. In politically sensitive taboo areas, where words can transform into creedal cudgels, there is much more at stake. PC language communicates a political attitude, and that is what makes its expression so volatile.

Taboo: Verbal Practices

F Merlan, Australian National University, Canberra, Australia

© 2006 Elsevier Ltd. All rights reserved.

'Verbal taboo' might be broadly conceived to comprehend a spectrum of linguistic practices ranging from euphemism, the deliberate 'softening' (Cameron, 1995: 73) through lexical substitution or other means of negative associations of words that deal with prohibited or stigmatized subjects, to more systematically structured replacement of normal forms that relate to such subjects as defined within particular speech communities, with other forms understood to specially index, and thus draw attention to, those very subjects and tokens of their occurrence. Despite the wide range of phenomena that might fall under this rubric, the designation '(verbal) taboo' has tended to be used mainly with reference to practices in which suppression and replacement of forms is extensive, highly systematized with reference to definable contexts of occurrence (normally both presupposed and configured by the usage), and accompanied by heightened consciousness and

objectification, including labeling or typification, of the practices involved on the part of members of the speech community. Nevertheless the difficulty of strict demarcation of an heuristic category of this sort necessarily remains. (For the entry of the term 'taboo' into Western circulation from Polynesian contexts see Shore, 1989; for its introduction into and circulation in scholarly usage, partly in the articulation of questions of civilization, development, and social order, see, e.g., Freud, 1913; Webster, 1942; Douglas, 1969).

Verbal taboo may be only one dimension of multimodal practices involving substitution of ordinary acts and linguistic forms by others that mark the relevance and structure the current situation of communication as one of a particular kind. Australian Aboriginal in-law avoidance practices mark contextual relevance or co-presence of persons in certain relationships through the use of avoidance language registers by those in the relationship (and also, to varying degrees, by others signaling their recognition of it). Special linguistic usages go along with a range of proxemic and other interactional markers: persons in certain relationships may speak but only observing the constraints of avoidance register; they may only face away from and never toward each other; they may accordingly not transfer things directly but preferably through third parties or through types of transfers that sometimes encode gender-based or other differentials between persons in the relationship. Similar respect or avoidance practices among the southern Sotho of southern Africa (Kunene, 1958) require that a daughter-in-law observe modesty before her father-in-law (and husband's other male relatives) in dress, in not suckling her baby in his presence, in not being close to him or touching him or his intimate property, in not using his personal name, and in using a respect language register, the extraordinary character of which is constituted, in part, by the use of (otherwise) obsolete Sotho words, and of borrowings from neighboring languages.

Australian avoidance language registers usually involve the substitution of a fairly small number of lexical forms by other forms that language-users recognize as belonging to the special register. Though claims about the extent of such substitute registers vary (see Dixon, 1971; Haviland, 1979; Rumsey, 1982), in many languages even more pervasive than lexical substitution was the use of register markers, affixed to or infixed in a wide variety of word classes, that served to repeatedly mark the situation as one of a particular kind (e.g., in Jawoyn (Djauan), Ngalakkan (Ngalakan), and other southern Arnhem languages the infix *-bong'-*, part of an avoidance register characterized by the use of adjectival and verbal designations emphasizing smallness, softness and delicacy of voice volume). Such "nonreferential indices" that "signal the structure of the speech context" (Silverstein, 1976: 30) cannot be characterized as different ways of saying the same thing in avoidance register as one would otherwise; they are not semantically equivalent to anything else because they have no semantic (i.e., denotational) value, only a situation-indexical, pragmatic one. There is also typically some modification of grammatical forms used to index interaction with avoidance relatives (e.g., nonsingular number for a single referent, a crosslinguistically ubiquitous way of marking deference and/or sociological distance, as noted, e.g., by Brown and Levinson, 1978, and Silverstein, 1976, 2003), and use of highly solicitous and nondirective speech, sometimes spoken as if directed to a third party but understood to relate to the avoidance relative's wants and activities. In Merlan (1997) such multimodal indices, far from literally amounting to avoidance, are taken as required indices of total orientation to the relationship.

Among kinds of denotational categories frequently subject to taboo are personal names (Frazer, 1911: 293–239). The marking out of personal names for taboo treatment is overdetermined in instances where this prohibition overlaps with the fact of affinal relationship to the name-bearer, and where taboo is enjoined, generally or upon certain categories of persons, following the bearer's death. In the Sotho case referred to (Kunene, 1958), in addition to using a respect register to her husband's father and male relatives, a woman does not use her husband's father's name (sensitivity concerning the use of affines' personal names is widespread cross-culturally), nor does she use words related or similar to his name (similarities in both sound and meaning are at issue), but may construct a referring term for him by using one of the standard respect vocabulary forms. For example, the name Mojapela (*ja* 'eat,' *pela* 'rock-rabbit') is substituted by a name composed of two respect (*hlonepha*) forms, Mofutatase (*futa* = hlo. 'eat,' *tase* = hlo. 'rock-rabbit'). Kunene (Kunene, 1958: 162) characterizes the broadest implications thus: where a man's name is Moeti, his daughter-in-law may be expected to avoid "not only the common noun *moeti* (traveller), but also *eta* ('travel'), *leeto* ('a journey'), *maeto* ('journeys'), *etela* ('journey towards, visit'), *etile* (perfect of *eta*), *etisa* ('cause to visit'), *etelana* ('visit one another')" – in other words, a range of grammatically, and lexico-semantically linked forms that the woman feels (Kunene, 1958: 162) are sufficiently similar to his name to warrant avoidance.

In Australian Aboriginal societies, the names of the recently deceased (however the pairing of person and name had been determined; the cultural sources and kinds of names were various) were/are tabooed, at least for a period of time (after which names are sometimes restored to use; see e.g., McKnight, 1975). Name tabooing usually seems to involve the suppression of homophones or words deemed similar to the name of the deceased. For Central Australia, Nash and Simpson (1981) document what they term a 'metapragmatic shifter,' a form /kumunjayi/ (and lectal variants) that serves as a regular substitute for the name of the recently deceased, any persons of the same name (such persons may, however, change their commonly used names following the death of a name sharer), and for a range of words or forms homophonous, or nearly so, with the name of the recently deceased person. Thus this single form may be used as the substitute denotational form for a recently deceased woman named Alice, as well as for the town of Alice (Springs), for example. Other forms of name substitutes are also innovated and disseminated, e.g., upon the death of a man named *Walpajirri*, which means 'hairy-nosed bandicoot'), is introduced the substitute descriptive term *ngarlkirdingarnu* '*Acacia sp*.-eater'). Nowadays, English given names are also among the kinds of names regularly replaced for a time by the general substitutive form /kumunjayi/.

Dixon (1971) uses the fact of many-to-one ratio of everyday (Guwal) to mother-in-law (Djalnguy) vocabulary in Dyirbal, north Queensland, to illuminate lexicosemantic description (e.g., of the differential markedness of transitivity in the two registers). Merlan (1982) shows how in Mangarrayi (Mangarayi), Roper River, Northern Territory, the avoidance register involves not only some lexical substitution of ordinary nouns (thus, roughly, retention of the ordinary grammar), but further, standard use of habitual verbal constructions in place of more direct referring expressions (e.g., 'the one who eats gum' instead of a single nominal expression for 'emu'). These examples of avoidance and taboo registers provide evidence for analysis of the pragmatic force of grammatical categories. (See also Meillet, 1921 and Bonfante, 1939 for examples of lexical and grammatical implications of word taboo in Indo-European).

Tabooing practices (linguistic and other) are widely reported for Austronesian speech communities (Simons, 1982). Keesing and Fifi'i (1969) summarize observances among the Kwaio, comprising about 6000 people of Central Malaita, Solomon Islands, at the time of study. Persons are members of descent groups, which are land-owning and ritual units. From ancestors of each group emanates power, which is a resource for the living. Ancestors vary in the degree to which they are venerated, and intensification of veneration occurs over time for only a few. Importance of a person at time of death is a factor correlated with eventual ancestral prominence, but only one. Propitiatory pigs, called *foʔota*, are consecrated to ancestors, and any individual's ritual position is largely defined by the pigs he raises. A dead ancestor is known by the name of *foʔota*, or pigs consecrated to him, in lieu of the name by which he (or a family cluster of ancestors) was known in life. In tabooing, then, at issue is not the name of the ancestor, but of substitute *foʔota* denotational forms, the use of which (and sometimes of related forms and euphemistic expressions, names of ancestral burial shrines) would be taken to infringe the sacredness of the ancestor (*adalo*) who had become an object of veneration for a descendant kin group. The prominence of an ancestor may accumulate posthumously according to the proliferation and spread of descendants who venerate him, in a kind of feedback mechanism. The potency of such an ancestor who has left many descendants may intensify until such time as the *foʔota* pigs dedicated in his name become so sacred that they may only be eaten by adult males of the descent group (and sometimes members of its nonagnatic genealogical segments).

Kwaio say the ancestor himself ordains tabooing of his *foʔota* name(s) and related forms, communicating this via divination, which is undertaken within the kin group following some illness or misfortune. Keesing and Fifi'i discuss name forms and view tabooing probabilistically rather than absolutely, the likelihood of tabooing varying with the singularity or generality of name forms, the grammatical category or categories of parts of names, cultural connotations of name bases, and other factors. Because a descent group shares an array of common ancestors and a locale (or set of locales), and tabooing becomes recognized as social fact in and following certain events (rituals, divinations, etc.) conducted in the name of the descent unit, processes of tabooing and related practices will have a recognizable spatial distribution. Certain other processes (kin group segmentation, outmarriage) will have consequences for the sociospatial distribution of word taboo. Keesing and Fifi'i briefly describe how those intending to visit a locale are warned not to use particular taboo forms to certain people, providing some insight into the ways in which taboos are sustained both by insiders and outsiders with respect to a localized descent group (and networks of associated people) as well as communicated across social space. Keesing and Fifi'i suggest that, while tabooing is widespread in Oceanic settings, the foci of sacredness and proscription are diverse and historically mutable. But a general principle

underlying practices of taboo, they suggest, may be a strength of relationship between a name and a person bearing the name (whatever particular kind of social fact a name may represent within a given social context, see Kripke, 1972; Diffloth, 1980 on names in Semai, Malaysia).

In Chinese and some other east and Southeast Asian languages, verbal taboo largely evokes the notion of words that are homophonous (sometimes this means segmentally but not tonally identical) with others that designate or connote something dangerous, feared or inauspicious. Avoidance of these is paralleled by practices of verbal preference: a word may be used because it sounds like another that has positive connotations. In Chinese the number four, *si*, is often avoided because it sounds like the word *si* 'die' (though these words have different tones, and their written characters differ). The number eight is highly preferred (in advertisements, business names, etc.) because it is a near homophone with the word 'get rich.' Pictures for birthdays and for New Year's often feature a picture of a large fish, because the word fish (*yu*) sounds like the word *yu* (abundance, prosperity). Similar kinds of avoidances and preferences obtain in Japanese and Vietnamese (Kindaiti *et al*., 1988; Ngô Đưc Thọ, 1997), underlain by the structural fact of abundant (segmental) homophony of words. While the structural fact of near or complete homophony is common to many languages (English among them), it is not everywhere the basis for such avoidance and preference. But where it is, these examples suggest there is a hierarchy of phonological characteristics that count for purposes of establishing near homophony, such that, for example, segmental phonology counts more than tone. There may also be some hierarchy of characteristics within segmental phonology. (See Haas, 1964 for discussion of issues of sound similarity interlingually).

In Japanese, *imi kotoba* 'taboo words' may be conditioned topographically, for instance, some ordinary words are proscribed and others substituted in the high mountains (hence an association with particular occupations such as hunting and woodcutting), and on the high seas. (Franklin, 1972 describes a ritual language used on Mt. Giluwe, Southern Highlands, Papua New Guinea, in association with the high-altitude harvesting of pandanus. This register is one of a number of forms of word tabooing that are ranged by the Kewa under practices of *sa pi agaa* 'hidden speech'). In Japanese, word avoidance is also triggered by the dissonance of certain word meanings with occasions: hence at a wedding speakers tend to avoid words meaning 'leave,' 'exit,' 'send back,' 'sever,' and 'suffer.' Sensitivity to occasion intersects with that toward homophony, conditioning the avoidance in business contexts of words such as *nashi* 'to have nothing, to nullify' and thus also of the homophone *nashi* 'pear' (Kindaiti *et al*., 1988).

In Chinese, homophonous taboo pairs (such as 'four' and 'die' above) remain paired across dialects, despite dialect differences in pronunciation, a stability conditioned by the constancy of the respective written forms across dialects (A. Kipnis, personal communication). For Sotho, Kunene (1958: 165) notes that a woman may write down words she avoids speaking, suggesting that a less direct pragmatic force is attributed to the written modality.

Verbal taboo involves a diverse set of practices, but also presents us with some cross-cultural regularities, e.g., in the nature of some of the metapragmatic characterizations of the practices involved (where softening, avoidance, etc. are common). It offers a series of pragmatic speaker-user evaluative and value-laden perspectives on belief and linguistic as well as other practice. It highlights issues in the circulation and standardization (or otherwise) of registers across social populations, the set of factors in relation to which linguistic taboos come to be recognized as social facts, the relation of linguistic and nonlinguistic dimensions of practice, and it offers a field for consideration of pragmatic and metapragmatic differences between written and spoken forms.

Tacit Knowledge

G S Rattan, University of Toronto, Ontario, Canada

As Louise Antony and Norbert Hornstein (2003: 6) suggest, two of Chomsky's most significant philosophical contributions lie in his revival of mentalism in the philosophy of mind and rationalism in epistemology. Linguistics is the study of the system of knowledge possessed by speakers both innately (*see* **Innate Knowledge**) and in the relatively steady state condition of linguistic maturity. This knowledge is a kind of tacit knowledge. The aim of this article is to clarify some of the psychological and epistemic aspects of tacit knowledge, primarily as it is relevant to Chomskyan linguistics. As a psychological attitude, tacit knowing is distinguishable both from garden-variety kinds of propositional attitudes like believing and desiring (what I call full propositional attitudes) and from nonpropositional states or skills typically classified as instances of knowing how. The epistemic role of tacit knowledge in the broader issue of knowledge of meaning is discussed, and a more positive understanding of tacit knowing, with its distinctively epistemic gloss, is tentatively offered.

The Early Debate

As Louise Antony and Norbert Hornstein (2003: 6) suggest, two of Chomsky's most significant philosophical contributions lie in his revival of mentalism in the philosophy of mind and rationalism in epistemology. Linguistics is the study of the system of knowledge possessed by speakers both innately (*see* **Innate Knowledge**) and in the relatively steady state condition of linguistic maturity. This knowledge is a kind of tacit knowledge. The aim of this article is to clarify some of the psychological and epistemic aspects of tacit knowledge, primarily as it is relevant to Chomskyan linguistics. As a psychological attitude, tacit knowing is distinguishable both from garden-variety kinds of propositional attitudes like believing and desiring (what I call full propositional attitudes) and from nonpropositional states or skills typically classified as instances of knowing how. The epistemic role of tacit knowledge in the broader issue of knowledge of meaning is discussed, and a more positive understanding of tacit knowing, with its distinctively epistemic gloss, is tentatively offered.

The Early Debate

It was clear to both Chomsky and his early critics that the kind of knowledge of language that speakers

possess, if any, is not explicitly held. Speakers do not know explicitly the general principles to which human languages conform, or the grammars of the specific languages of which they are speakers. Chomsky and his early critics differed, however, on what they took to be the implications of that straightforward idea.

Critics argued that the invocation of psychological attitudes, especially knowing, was at best misleading and at worst wrong. The general objection is that the cognitive relation involved in the explanation of linguistic capacity, if indeed there is such a cognitive relation, cannot be that of knowing, because that cognitive relation does not sustain the connections constitutive of knowledge (see, e.g., Stich, 1971: §4; Quine, 1972: 442; Devitt and Sterelny, 1999: 139; Dummett, 1991: 95–97). More specifically, early critics held that the states that underlie our ability to use language are, for most competent speakers, wholly unconscious, and when known, say by linguists, are known only indirectly through scientific theorizing. But, they contend, if one is to be ascribed a certain piece of knowledge, that knowledge should be recognizable 'from the inside' and not merely ascribable as a result of scientific theorizing. Let us says that having a full propositional attitude is constrained by a 'self-knowledge constraint,' according to which self-knowing is a distinctive, nontheoretical way of coming to know of one's attitudes and their contents.

Chomsky considers such objections (Chomsky, 1980, 1986) and replies as follows:

> I have been speaking of "knowing English" as a mental state . . . [But] to avoid terminological confusion, let me introduce a technical term devised for the purpose, namely "cognize," . . . In fact I don't think that "cognize" is very far from "know" . . . [Cognizing] is tacit or implicit knowledge, a concept that seems to me unobjectionable . . . Cognizing has the structure and character of knowledge, but may be and in the interesting cases is inaccessible to consciousness. (Chomsky, 1980: 70–71)

The thrust of Chomsky's answer, then, is that if 'knowledge' offends, a technical term can be employed whose sense lacks precisely the offending features; but, continuing the response, the theoretical concept thereby introduced ought not to be thought of as fundamentally different from knowledge: it is knowledge, but it is unconscious, or not self-known.

Tacit Knowing vs. the Full Propositional Attitudes

We can see here an oversimplification of what might be involved in an account of the nature of propositional attitudes. There seems to be room to acknowledge both that speakers' knowledge of language does not sustain the connections constitutive of knowledge and the full propositional attitudes and that, nevertheless, tacit knowledge is unobjectionable. The debate is oversimplified in turning only on a single, blunt constraint of self-knowledge. In what follows, I will try to enrich the debate by indicating considerations for thinking of tacit knowing as a propositional attitude without construing it as a full propositional attitude.

What more might be added to the understanding of the fully propositionally attitudinal to bring out its deep constitutive differences with tacit knowing? To begin with, we may take note of a pervasive feature of cognitive psychological theorizing, namely, that it construes the mind as modular: as segmented into mental components that use systems of encapsulated information that are inaccessible to conscious thinking, that are dedicated to representing highly structured or eccentric domains, and whose deployment is fast and mandatory (cf. Fodor, 1983). For the proponent of the idea that knowledge of language is a kind of tacit knowledge, the language faculty is itself, to a first approximation, such a modular system (Chomsky, 1986: chapter 1 [especially note 10]; Higginbotham, 1987; *see* **Cognitive Science and Philosophy of Language**).

The general properties of modular systems stand in sharp contrast with basic properties of the full propositional attitudes. The full propositional attitudes are inferentially integrated (Stich, 1978; Evans, 1981) and so can draw upon, and can be drawn upon, by a range of other full propositional attitudes (so they are neither encapsulated nor inaccessible) without regard to subject matter (so they are not dedicated). Although belief fixation may not be voluntary, it seems not to be mandatory in the sense in which the operation of modular systems is. The latter is a compulsion by psychological law; the former is something like a compulsion by reason (more on this below). Finally, the operation of the full propositional attitudes can be painfully slow. Reasoning can take a long time. These differences show that, on its own, the self-knowledge constraint is quite incomplete as to what is distinctive about the way that the information contained in the language faculty is held.

The point about modularity concerns primarily the nature of the attitude of tacitly knowing. But consider as well what Gareth Evans (1982) has called the 'generality constraint,' which pertains to the objects of the full propositional attitudes, thoughts or propositions, and their constituents, concepts (*see* **Concepts**). According to the generality constraint, concepts possess an inherent generality that mandates their recombinability with appropriate concepts of

other logical categories; slightly more formally, thoughts are closed under logico-syntactic formation rules, up to conceptual incoherence or anomaly (cf. Peacocke, 1992: 42).

Now, no explanatory point seems to be served by imposing such a constraint on the representation of the information deployed in the language faculty. Speakers tacitly know the grammar that they do; knowledge of that grammar is deployed in some way or other, through the actions of mechanisms implementing algorithms that deploy the grammatical information tacitly known, so as to allow the acquisition, production, and perception of linguistic forms. Insisting that the constituents of the representation of linguistic information be subject to the generality constraint in no way illuminates the explanatory role of tacit knowing.

The reason can be clarified by thinking about the basic theoretical aims and motivations for both the full propositional attitudes and their contents. The full propositional attitudes and their contents are the fundamental theoretical entities in the conceptualization and explanation of the epistemic and practical successes and failures of agents. The explanations trace and assess the complexes of reasons for which agents believe and act, and implicitly evaluate those complexes, and agents, against an ideal of rational epistemic and practical functioning. The notions of epistemic and practical responsibility get their grip here, in the gap between actual and ideal. Since rational inference requires the interactions of attitudes and the recombination of concepts in a variety of ways, attitudes and contents must be such as to sustain the actual evaluations of epistemic status of agents in their inferential practices (Rattan, 2002: §4). The requirements that the full propositional attitudes be inferentially integrated and that concepts obey the generality constraint reflect these normative dimensions of the roles of attitudes and contents.

These ideas suggest, then, a deep point of contact with the self-knowledge constraint: that constraint will be relevant, like inferential integration and generality, insofar as it reflects fundamental features of rational practice. And surely it does. Reflecting on one's attitudes is a way of increasing the rational status of those attitudes. But if reflection plays that rational role, then it must be that our access to our attitudes is reliable and possessed of entitlement (cf. Burge, 1996); our access to our own minds must in the most basic cases be knowledge. Demanding that the attitudes and their contents be self-known, then, is part of a general account of the full propositional attitudes and their contents that construes them so that they may play their role in conceptualizing and explaining the normative statuses of agents.

Tacit Knowing vs. Knowing How

But it may be objected that for all that has been said so far, tacit knowing may not be a kind of content-bearing state at all; given the deep differences between tacit knowing and the full propositional attitudes, tacit knowing simply seems not to be a genuine mental attitude toward contents.

The objection can be elaborated by insisting that speaking a language is not a matter of knowing propositions at all. As Michael Devitt and Kim Sterelny put it:

> [C]ompetence in a language does not consist in the speaker's semantic propositional knowledge of or representation of rules. It is a set of skills or abilities . . . It consists in the speaker being able to do things with a language, not in his having thoughts about it. (Devitt and Sterelny, 1999: 187)

Perhaps there are no states of knowing the facts about the language – no knowing the rules or grammar of the language. A speaker no more knows the rules of the grammar than one who can ride a bike knows the laws of mechanics governing balance and maneuver. The language faculty is a faculty of knowing how to speak a language. Call the proponent of such a view the 'knowing-how theorist.'

Of course it cannot be denied that speakers do know how to speak the language; but the knowing-how theorist must justify the idea that attributions of knowing **how** are not just species of attributions of knowing **that**, as certain syntactic and semantic evidence suggests (Stanley and Williamson, 2001). Again, it looks as though the knowing-how theorist simply misses the point: although speakers know how to speak the language, that is not an explanation, but a description of what needs to be explained (cf. Higginbotham, 1994). But let us suppose that the knowing-how theorist is proposing an alternative explanation, one that does not appeal to tacit knowing. The knowing-how theorist has at least two significant hurdles to overcome.

First, suppose it is granted that tacit knowing does not have the direct role in rationalizing conceptualizations and explanations that the full propositional attitudes do. There still seems to be nothing to prevent thinking of tacit knowings as having the same attitude-content structure that the full propositional attitudes do. The attitude is not, admittedly, understood as playing a certain rational role, but it still may have a regular and lawlike causal role, and that would seem to be enough to think of there being something attitude-like – a distinctive way in which the information is held – in the picture. (Indeed this is the usual understanding of the attitudes in causal functionalism;

see, for example, Lewis, 1972.) This, for example, is what we might like to say about animals and their attitudes. They fail to have states that satisfy the normative constraints that the full propositional attitudes do, but it would be theoretically heavy handed to say that they do not have states that are very much belief- and desire-like.

Again, serving the aims of rationalizing explanations may require that contents be individuated at the level of Fregean sense rather than reference; this is the point of 'Frege's Puzzle' (Frege, 1892). But if tacit knowings fail to figure directly in these kinds of rational phenomena, then their contents may legitimately be exempted from having the general properties that the contents of attitudes that do so figure must have. The contents of tacit knowings may be Russellian, or have a limited need for cognitive difference without difference in reference (*see* **Sense and Reference: Philosophical Aspects**). These constituents of contents, objects and properties, presumably do not obey the generality constraint, so there are ways in which contents may be involved yet fail to be like the contents of the full propositional attitudes. The issues here are complex, and I mean only to flag the general issue about the individuation of the contents of tacit knowings and how that may serve to distinguish them from the contents of the full propositional attitudes.

Second, perhaps the proponent of knowing how thinks that the explanation of linguistic ability is merely dispositional, like the explanation of the shattering of a glass by appeal to its fragility. Here, there is some categorical, microstructural, property of the glass that, simplifying tremendously, explains why in conditions of the appropriate sort, the glass shatters. In a like manner the knowing-how theorist may appeal to the categorical neurophysiological ground of linguistic dispositions as comprising a nonintentional explanatory level. This idea, however, is subject to all the general objections that favor functional explanations over neurophysiological ones. It neglects a tradition of thinking about psychological explanations as involving multiple – computational, informational, algorithmic, and implementational – levels (see Marr, 1982; Peacocke, 1986). Indeed the functional states will be realized by neurophysiological states, but the explanation will be cashed out at some level that abstracts from neurophysiological description.

What Is Tacit Knowledge?

So far tacit knowing has been negatively characterized, by being distinguished from both the full propositional attitudes and knowing how. But how are we to understand the nature of tacit knowledge in more positive terms? Tacit knowing plays a role in the explanations of linguistic acquisition, perception, and production. The described capacities are epistemic in character. Their explanations are part of more elaborate explanations that seek to understand the general phenomenon of communication, including its substantial pragmatic elements. To keep the discussion manageable, I will ignore the more elaborate problems. As well, I will focus only on the problems of linguistic perception and linguistic production. I mean only to gesture roughly at the kinds of considerations that are involved.

According to these explanations, speakers are able to make knowledgeable sound-meaning pairings for sentences because they have information about the phonological, syntactic, and semantic – grammatical – properties of the expression-types that make up those sentences. This information is drawn on by perceptual and production mechanisms. Simplifying immensely, production mechanisms take inputs from intentions to say that p, and make available to a speaker, through the use of the grammatical information, expression types that mean that p. Perceptual mechanisms take acoustic inputs and, through the use of grammatical information, impose grammatical properties on them, eventuating in an experience of meaning, on the basis of which meaning judgments are made (cf. Fricker, 2003). A fully fleshed out epistemology of meaning would explain the epistemic differences between knowing one's own meaning in production and knowing others' meanings in perception by, for example, considering how the inputs to production and perception, respectively, allow for different kinds of mistakes in the eventuating judgments about meaning.

Let us assume that information is deployed in speakers' linguistic epistemic achievements (so these achievements are not examples of knowing how), and that this information is tacitly rather than explicitly held (so it is not an example of a full propositional attitude). Still, why must we accept that this information is known rather than just truly believed? The question is difficult and fundamental. I offer here some potential lines for understanding.

Suppose, as I have been suggesting, that tacitly held information or content is involved in the explanation of linguistic capacities. Two things are of note here about this information. First, these representations have been formed by a reliable mechanism – one that uses speakers' innate representations of Universal Grammar – that reproduces the grammatical information represented in the minds of speakers in one's community. In normal environments, acquiring these representations will equip one to come to judge

knowledgeably the meanings of other speakers. Second, once one moves away from folk conceptions of public language, it is plausible to think of the facts about which language one speaks as settled by one's grammatical representations or I-language (Chomsky, 1986: Chapter 2; Higginbotham, 1991; Barber, 2001; *see* **E-Language versus I-Language**). Judgments about what one means oneself will then be reliably produced, again as outlined above; and since the facts about one's language are determined by one's grammatical representations, they will be reliably produced by the facts that determine the language one speaks. It seems that as a phenomenon at the level of the full propositional attitudes, knowing our own meanings and knowing the meanings of others, when we do, is not an accident.

We can think of the foregoing as giving the outlines of a philosophical explanation of what might be called the success-presupposing features of the explanation of our linguistic capacities. The explanations are not success neutral (see Burge, 1986, who attributes the phrase to Bernard Kobes), in that the explanations are explanations of epistemic capacities that are generally presumed to be successful. But if that is right, we are in a position to say something about why the information tacitly held is knowledge. Unless that information were known, rather than just truly believed, it would seem to be a mystery why drawing on that information in perception and production leads in general to knowledge. So one suggestion is that the status of the information as knowledge comes from the distinctive explanatory role of the tacitly held information in explanations of our generally epistemically successful linguistic capacity.

That's one pass at vindicating the attribution of knowledge. But perhaps something deeper can be said. Here we can return to Chomsky's rationalism. Sometimes Chomsky's rationalism seems to be a genetic rationalism that emphasizes the innate character of Universal Grammar, vindicating an early modern doctrine of innate ideas (*see* **Innate Ideas**). But there is another way to think of this rationalism, in which it emerges as a more full-blooded epistemic doctrine. In this way of thinking, at some point in the evolution of humankind, minds came into a cognitive relation with certain abstract structures, with very valuable combinatorial properties. These abstract structures are languages. We have already seen that the tacit is not the realm of epistemic and practical responsibility. So the status of knowledge for tacit representations will not accrue as a result of some personal-level achievement. The status of knowledge for the representations that underlie our linguistic capacity derives instead from a natural attunement of the modular structures of the human mind to the abstract combinatorial structures of language.

Tadadjeu, Maurice (b. 1950)

U Seibert, University of Giessen, Giessen, Germany
U Wiesemann, Dietzhölztal, Germany

© 2006 Elsevier Ltd. All rights reserved.

Maurice Tadadjeu was born in 1950 in Dschang into an important family among the Yemba people. Early in school, he wondered why he had to study French wars – what would that help him do? His nationalist pride in Cameroonian identity and language had begun. At Libermann College, he became a leader in the Boy Scout movement which taught him the principles of leadership. The college developed a language program in which he could document his mother tongue Dschang (Yemba). So he opted to study linguistics. During a scholarship program in the United States, he discovered pan-Africanism, which opened his mind to the possibilities of Language Planning in his own country.

Upon return to his country in 1978, he started talking to his friends, particularly those in government, about his vision of studying the African languages spoken in Cameroon. In 1979 he organized the first meeting of representatives of all languages to agree upon symbols with which to write their languages. As a result, it was discovered that in fact there are more than 250 African languages spoken in Cameroon, representing all the major language families on the continent. To explore possibilities of developing writing systems and school materials he created PROPELCA (Projet de Recherche Opérationnel pour l'Enseignement des Langues au Cameroun). With great imagination and creativity the group developed strategies on how to go about changing attitudes of authorities toward a policy of mother tongue education in schools – mainly Tadadjeu's contribution – developing writing systems, testing them by writing school materials, training schoolteachers, finding schools and parents willing to let their children participate in such teaching in the mother tongues, previously unthinkable in Cameroon (though not in other African countries).

It took only two years to achieve the first positive results: the children could learn English or French better if taught the basis of reading and writing in their mother tongue. At the end of the school year, they had learned more of the official language than the children who were taught monolingually in the foreign language. This project gave impulses and ideas to generations of students in the Linguistics Department, spurred dissertations, and slowly changed the attitude of a whole nation. As a result of Tadadjeu's lobbying, in 1996, the new Cameroonian Constitution admitted the existence of Cameroonian languages and guaranteed the right to their use in schools. In 1998 a law was created to that effect.

Cameroonians are regaining pride in their heritage and mother tongues. The vision and untiring efforts of Maurice Tadadjeu are being heard in Africa and beyond. In this way the results of his inspiration and personal efforts are slowly changing the African continent, giving place to the rich cultural heritage of the many African people groups, their thinking expressed in their languages, and at the same time making place for the people with such values to work together, to become true multilingual nations that pull together because they find it advantageous to do so.

Tagalog

J U Wolff, Cornell University, Ithaca, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Tagalog, spoken in the Philippines, is a member of the Austronesian group of languages. The Austronesian languages are descended from Proto-Austronesian, which is believed to have developed on the Asian mainland and to have been brought to Taiwan by around 6000 B.C., whence its descendents spread through the Philippines and Indonesia eastward to the islands of the Pacific. The earliest documents in Tagalog date from a few decades after the first Spanish colonization in 1564. The pre-Hispanic Tagalogs had a syllabary called *Alibata*, which has been recorded, but if there was any written literature, none of it survives. The end of the 16th century and the beginning of the 17th saw the publication of a catechism *Doctrina Cristiana*; a magnificent and thoroughgoing dictionary, a grammatical description, and a textbook that purports to teach Spanish to Tagalog speakers. These provide good documentation of what Tagalog was like at the time, and indeed the language of these texts is readily understandable today. Other literature, mostly poetry, dates from the middle of the 19th century. It was only in the beginning of the 20th century that prose literature and other types of writing were published in Tagalog. Education in the medium of Tagalog was not introduced until the 1960s, and to this day, English predominates as the medium of instruction at all levels.

Tagalog has a unique status among the more than 100 indigenous languages of the Philippines in that it is the national language alongside of English. Although English still predominates in the Philippines as the language of education, public affairs, and formal occasions, Tagalog is increasingly coming into use in these settings, particularly in those areas in which Tagalog is spoken natively. At the time of the Philippine Commonwealth, Tagalog was spoken by less than a quarter of the population of the Philippines. To avoid political controversy among the speakers of other languages, the fiction was adopted that this language, with some modification of vocabulary taken from other major Philippine languages, was an amalgam of these languages. As such it was called 'Pilipino.' In the 1970s, a new fiction was adopted, that the amalgamation of Philippine languages that was to serve as the national language was composed of a larger number of the indigenous languages than Pilipino had been, and this new language was termed 'Filipino.' However, the terms 'Pilipino,' 'Filipino,' or 'Tagalog' all refer to one and the same language, and all three terms are commonly used to refer to it.

Tagalog is spoken indigenously in the Manila region and in the provinces surrounding it. As such, it is the language associated with the seat of Philippine power and culture, and has acquired a special cachet or prestige. In the last few decades, Tagalog has spread far beyond its original home to urban areas to the south and the north, especially those that have seen a large influx of immigrants from other regions, although in Mindanao there is strong competition from Cebuano, and in the north competition from Ilocano. However, at this point, Tagalog has become the native language of approximately one-third of the population of the Philippines and is ever increasing in number of speakers. In addition, Tagalog press, TV, and cinema, and most importantly, population mobility, have spread the knowledge of Tagalog throughout

Tagalog, spoken in the Philippines, is a member of the Austronesian group of languages. The Austronesian languages are descended from Proto-Austronesian, which is believed to have developed on the Asian mainland and to have been brought to Taiwan by around 6000 B.C., whence its descendents spread through the Philippines and Indonesia eastward to the islands of the Pacific. The earliest documents in Tagalog date from a few decades after the first Spanish colonization in 1564. The pre-Hispanic Tagalogs had a syllabary called *Alibata*, which has been recorded, but if there was any written literature, none of it survives. The end of the 16th century and the beginning of the 17th saw the publication of a catechism *Doctrina Cristiana*; a magnificent and thoroughgoing dictionary, a grammatical description, and a textbook that purports to teach Spanish to Tagalog speakers. These provide good documentation of what Tagalog was like at the time, and indeed the language of these texts is readily understandable today. Other literature, mostly poetry, dates from the middle of the 19th century. It was only in the beginning of the 20th century that prose literature and other types of writing were published in Tagalog. Education in the medium of Tagalog was not introduced until the 1960s, and to this day, English predominates as the medium of instruction at all levels.

Tagalog has a unique status among the more than 100 indigenous languages of the Philippines in that it is the national language alongside of English. Although English still predominates in the Philippines as the language of education, public affairs, and formal occasions, Tagalog is increasingly coming into use in these settings, particularly in those areas in which Tagalog is spoken natively. At the time of the Philippine Commonwealth, Tagalog was spoken by less than a quarter of the population of the Philippines. To avoid political controversy among the speakers of other languages, the fiction was adopted that this language, with some modification of vocabulary taken from other major Philippine languages, was an amalgam of these languages. As such it was called 'Pilipino.' In the 1970s, a new fiction was adopted, that the amalgamation of Philippine languages that was to serve as the national language was composed of a larger number of the indigenous languages than Pilipino had been, and this new language was termed 'Filipino.' However, the terms 'Pilipino,' 'Filipino,' or 'Tagalog' all refer to one and the same language, and all three terms are commonly used to refer to it.

Tagalog is spoken indigenously in the Manila region and in the provinces surrounding it. As such, it is the language associated with the seat of Philippine power and culture, and has acquired a special cachet or prestige. In the last few decades, Tagalog has spread far beyond its original home to urban areas to the south and the north, especially those that have seen a large influx of immigrants from other regions, although in Mindanao there is strong competition from Cebuano, and in the north competition from Ilocano. However, at this point, Tagalog has become the native language of approximately one-third of the population of the Philippines and is ever increasing in number of speakers. In addition, Tagalog press, TV, and cinema, and most importantly, population mobility, have spread the knowledge of Tagalog throughout

the nation, so that only few people, and those mostly in the oldest generation, do not have at least a passive knowledge of Tagalog. Further, although loyalty to the native language is strong in the Philippines (few of the indigenous languages are in danger of dying, even though some have small numbers of speakers), it is becoming increasingly acceptable to use Tagalog in social settings (even in non-Tagalog regions), where family members and guests use Tagalog instead of the native language. This usage usually occurs on the part of native sons, who have moved to Tagalog-speaking regions for employment, or their children. Many have become dominant in Tagalog. Speaking in Tagalog in a group where everyone else is speaking the native language is not remarked upon, and in fact, there is a certain prestige attached to speakers who do this, as it is a sign of having made good in the outside world. Abroad, Tagalog has become the mark of Philippine national identity and is used by Filipinos with other Filipinos, no matter what region they come from, and internally, Tagalog is well on its way to becoming the lingua franca of a multilingual nation.

What Tagalog Is Like

Tagalog has a simple phonology. The consonants, vowels, and diphthongs are as follows (Table 1). Note that there are long and short vowels: the long vowels are marked with an accent.

Glottal stops in standard Tagalog occur only before a pause. If a word with a glottal stop at the end of it occurs in a phrase with another word following it, the glottal stop is lost, and there is compensatory lengthening of the preceding vowel:

> *Walaʔ* 'not' + *na* 'any longer' produces *walá na* 'no longer'

The spelling system ignores important parts of the phonology and does not recognize long versus short, although pedagogical texts use a cumbersome system to indicate these partially. The system also does not indicate /ʔ/. The palatals /c/, /j/, and /ʃ/ are written *ts*, *dy*, and *sy* respectively. The phoneme /ŋ/ is written *ng:*

> /cinílas/ *tsinilas* 'slippers'; /jip/ *dyip* 'jeep';/ʃa ŋ á pala /*sya nga pala* 'by the way'

Table 1 Tagalog phonology

Consonants					*Vowels and Diphthongs*			
p	t	(c)	k	ʔ	i,í			u,ú
b	d	(j)	g	h	(e, é)		(o,ó)	
m	n		ŋ			a,á		
	s, ʃ				iw			uy
w	l, (r)	y					ay, aw	

At the time the Spaniards first came to the Philippines, Tagalog clearly did not have this phonological system. The phonemes in parentheses in Table 1 show sounds that have been added to Tagalog since that time. This addition is proven not only by comparing Tagalog with other Philippine languages (i.e., doing historical reconstruction) but also by the treatment of loanwords from Spanish at the early time and the modern time. An example is the Spanish word for 'hat' *sombrero*, which was borrowed twice in Tagalog: once early on and then again later. These two words are now perceived to be two different lexical items and refer to different things, but their phonemic make-up show how Tagalog has expanded its phonology: it has added /o/ and /e/, it has come to allow a consonant clusters with /r/, and has come to allow a vowel other than /a/ to occur three or more syllables from the end:

> *sambalílu*ʔ, 'conical sun hat of the native variety' *sombréro* 'western hat'

Not all of this is due directly to Spanish influence. Much has to do with internal developments in Tagalog itself, but the contact with Spanish was a catalyst or facilitated some of these developments, in that Spanish words pronounced closer to the Spanish pronunciation made certain rare combinations or types more common.

In grammar, Tagalog is characterized as a synthetic rather than an analytic language (English is an example of an analytic language). In Tagalog, single words containing a root plus affixes of all sorts express what in analytic languages would be expressed by a phrase. For example, the single word *pápapagparikitin* 'will cause him or her to make a fire' expresses what in English takes seven words to express. The root here is *dikit* (the initial /d/ is changed to /r/ by rule that says /d/ between vowels is often changed to /r/).

The verbal system in Tagalog expresses the relation between the verb and a word it refers to: the word referred to may signify the agent, the place, the beneficiary, the instrument, the patient, the thing moved, or the indirect object (depending on the affix). The verb contains what in English would be a verb and a preposition. An example is the root *pútol* 'cut':

(1) (agent) Ako ang ***púpútol***
I the-one-who will-cut
nang táliʔ.
object-maker string
'Let me be the one ***to cut*** the string.'

(2) (patient) ***Putúlin*** mo ang táliʔ.
Cut-it by-you the string
'***Cut*** the string.'

(3) (local) ***Putúlan*** mo nang
Cut-from-it by-you object-marker
kóntí ang kék.
little the cake
'***Cut*** a little ***from*** the cake.'

(4) (benefactive) ***Ipútol*** mo
Cut-for by-you I
ako nang kék.
object-marker cake
'***Cut*** the cake ***for*** me.'

(5) (instrumental) Itong kutsilyo ang
This knife the-one-that cut-with-it
ipangpútol mo
by-you on string
'***Cut*** the string ***with*** this knife.'

Cutting across this system of voice or prepositional-like affixes is a system of four-way inflections that expresses time (past or present as opposed to future), ongoing or iterative action, as opposed to a single action, and an imperative inflection, which is also used to express dependence, optatitivity or uncertainty. For example, sentence (1) above exemplifies future tense, (6a) below exemplifies noncompleted action, (6b), past action, and (6c), uncertain action:

(6a) Ako ang láging
I the-one-who always cut
púmupútol nang táliʔ.
object-maker string
'I am the one who is in charge of cutting (literally, always ***cuts***) the string.'

(6b) Síno ang
Who the-one-who did-cut
pumútol nang táliʔ?
object-maker string
'Who (purposely) ***cut*** the string?'

(6c) Baká ***pumútol*** siya nang táliʔ.
lest cut he object-marker string
'He ***might*** just ***cut*** the string.'

Perfective action is not expressed by verbal inflections but rather analytically (by a phrase).

(6d) Matagal **na** akong
long-ago has-been I
pumútol nang táliʔ.
cut object-maker string
'It **has been** some time since I (*purposely*) *cut* the string.'

(6e) Alas sayis **na** ako
o'clock six have-done I
púpútol nang táliʔ.
will-cut object-maker string
'At six o'clock I ***will have cut*** the string.'

There is a large number of derivational affixes that interact with the above-mentioned inflectional affixes to produce verbal forms with a wide number of meanings. Some of these affixes are applicable to almost all roots, some are more limited in their distribution. The most productive are the causative affix *pa-* and the potential affix *ka-*, both of which are addable to almost all roots that take verbal affixes. More than one derivational affix may occur within a verb. There are affixes that transitivize intransitive verbs, others that form verbs of reflexive action, those that form plurals, those that indicate an action done by two together, by more than two together, actions done as a favor, actions involving another, actions done by accident, and so forth. There is also a large number of adjective and nominal derivations.

Here are a few examples from the root *sáma*, a small percentage of the total number of derivational forms that occur with this root:
No derivational affix, 'go along':

(7) Ayó kong ***sumáma***
not-want I go-along
'I don't want to ***go along***.'

With *pag-*, transitivizer: 'take something. along somewhere':

(8) ***Magsáma*** [=-um-+pag + sáma] ka nang
Bring-along you object-marker
táʔo pagpunta mo doʔ on.
person when-go you there
'***Bring*** someone ***with you*** when you go there.'

With *pa-*, causative:

(9) Hindí mo siyang dápat
Not by-you him should
pasamáhin.
cause-him-to-accompany
'You should not ***allow him to come along***.'

With *ka-*, potential action:

(10) Hindí ka ***makákasáma*** [=future active + potential + sáma]
Not you will-be-able-to-go-along
kung íiyak ka.
if cry you
'You won't ***be able to come*** along if you are going to cry.'

With *kápa-*, accidental and causative action:

(11) ***Nápasáma***[= past-passive + ká- accidental action + pa- causitive + sáma] yung
Was-accidently-caused-to–go-along that
papel sa dala-dala ko
paper with thing-brought my
'I accidentally took that piece of paper together with the thing I was bringing (That piece of paper ***got caught up with*** the things I was bringing)'.

With *pag-*, 'do together':

(12) San Miguel, ang bir na may
San Miguel the beer that there-is
pinagsamáhan [= past + local-passive + pag- + sáma].
be-companions-over-it
'San Miguel, the beer people have ***companionship over (while drinking).***'

Influences on Tagalog and Tagalog's Influence on Other Languages

Tagalog, as a language of wider communication and as a spreading language, is being simplified. Simplification is most marked in urban areas, and the process is gradually spreading to the provinces. It undoubtedly begins from errors made by people (immigrants from non-Tagalog regions or Filipino Chinese) who learn Tagalog as a second language and are imitated by native speakers. One simplification is the loss of contrast between long and short vowels in certain syllables, leading to the loss of contrast between the accidental and the potential conjugations, e.g., *nápasáma* of example (11) above is pronounced /napasáma/ (which in conservative Tagalog has no meaning). Similarly, *mábibili* 'someone might buy it' (the accidental passive future) is pronounced /mabíbili/. Thus, the contrast is lost between *mábibili* 'someone might buy it' and *mabíbili* 'is able to buy it' Another aspect of this simplification is that there is a tendency to drop many of the productive derivations, which are very much alive in conservative Tagalog and exclude any vocabulary but that of the highest frequency. This tendency is exacerbated by the secondary role of Tagalog *vis-à-vis* English in public life and in education.

Mutatis mutandis, Tagalog influences the other indigenous languages of the Philippines. These other languages are replete with Tagalog loanwords that stem from the language's widespread use in the media. In some areas, Tagalog has a more intimate effect. In Samar, for example, where a large portion of the population has work experience in the Manila area and Manila has an especial cachet, the regional language is spoken by many younger people with a clearly observable Tagalog intonation. In the urban parts of the Cebuano speech area, where the managerial class is largely composed of immigrants from Tagalog regions who have learned Cebuano as a second language, complexities of Cebuano syntax that have no analogue in Tagalog are lost or regularized, and this syntax has spread to the younger generation of Cebuano natives who have no Tagalog connection (*see* **Cebuano**).

Tagliavini, Carlo (1903–1982)

P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Born in Bologna on June 18, 1903, Carlo Tagliavini studied law, Romance philology, and linguistics (*glottologia*) at the University of Bologna. As a student he learned Rumanian and published a grammar and reader of this language in Germany when he was only 20 (1923a, 1923b). In 1924, he obtained his Ph.D. with a thesis on comparative grammar. In 1926, he published a monograph on the Ladin dialect of Comelico; throughout his life, he remained strongly attached to the Ladin dialects. For a period he was a lecturer in Bologna (1926–1927), lecturer for Italian and Spanish in Nijmegen and Tilburg (1927–1929), and professor of Romance linguistics in Budapest (1929–1935); in 1935, he was appointed professor of linguistics and Romance philology (occasionally also Germanic philology) at the University of Padova, where he stayed until his retirement in 1973, and where he formed many generations of Italian linguists and Romance scholars. He died on May 31, 1982 in Bologna.

Tagliavini was a specialist of the Romance languages, especially of Italo–Romance, Rhaeto–Romance (Rhaeto–Romansch), and Balkano–Romance (he also published on Spanish and Portuguese), but he was equally well at home in Germanic philology and general linguistics. In the 1920s, he also published articles on American Indian languages (Chiquito [Chiquitano] and Luiseño). As a result of his well-organized teaching at Padova, he produced a number of carefully documented and comprehensive manuals of Romance linguistics (1st edn. 1949), Germanic philology (1968), Italian linguistics, general linguistics (1936), and also of Latin historical phonology and morphology. These manuals contain a wealth of bibliographical references, and systematically organized factual information. The manual of Romance linguistics was updated and revised by the author over a period of some 25 years; it was translated into German and into Spanish, and is still used as a textbook for courses in Romance linguistics. Tagliavini had an active or passive mastery of a wide variety of languages (Indo–European, Semitic, and Finno–Ugric), and possessed an encyclopedic knowledge of the language sciences (he contributed important linguistic entries to the *Enciclopedia Italiana*, and he was the author of a linguistic chronicle in the popularizing journals *Le lingue estere* and *Oggi*). He took a keen interest in the history of linguistics (especially in empirical achievements; cf. 1963 and 1968), and had compiled a very rich archive of photographs of linguists. Tagliavini showed special interest in historical and comparative linguistics; the diachronic perspective underlies his dialectological work on Ladin (1926, 1934, 1944) and Albanian (1937), and his onomastic studies (1957, 1981).

Tagmemics

B L Edwards, Bowling Green State University, Bowling Green, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Tagmemics refers to a species of structural linguistics that eventually outgrew the tenets of its own categorization as a 'slot and class' grammar, and now inhabits an eclectic space in linguistic history and inquiry that defies easy labeling. Its theoretical foundations are derived primarily from the research and methodologies of American linguist Kenneth L. Pike (1912–2000).

Tagmemics is founded upon the conceptualization of the 'tagmeme.' In its original meaning, tagmeme (by way of Leonard Bloomfield) referred to the smallest meaningful unit of grammatical structure in a language. In Pike's reformulation, the tagmeme becomes simply any 'unit in context,' and may denote any item or phenomenon in human communication, whether phonological, morphological, syntactical, or rhetorical (i.e., 'above the sentence') – or, indeed, beyond language use itself, in the behavior of the human community at large.

For Pike, a tagmeme is to be described in terms of four component features or cells: slot (where the unit may or must appear), class (what type or kind of unit it is), role (the rules that govern or describe how the unit functions), and cohesion (the relationship between the unit and other units and how they interact and influence each other). 'Slot' is related to position; 'class' comprises a set of replaceable/substitutable elements; 'role' refers to purpose and the impact of the unit in its location; and 'cohesion' is the relevant background that offers constraints and correlations for components of the tagmeme. A simple tagmemic analysis of the sentence, *Joan hit Michael* would look like this:

> *Joan* is a member of the class Proper Noun Root, and fills the Subject slot of Actor; whereas *Michael*, another member of the class Proper Noun Root, fills the slot of Adjunct (or Object), which has the role of Undergoer. *Hit* serves in the slot of Predicate and conveys Action in its role. Cohesion is involved in this analysis by providing the background information that illuminates such features as verb tense, number in subject, etc.

Put simply, tagmemic linguistic inquiry produces a series of four-celled analyses that identify the function of constituent tagmemes within a particular language phenomenon, e.g., a sound, word, sentence, or text that facilitates the movement from an 'etic' or outsider view toward an 'emic' or insider view of the subject of the inquiry.

Pike began his linguistics career as a virtually self-taught translator among the Mixtec of Mexico, eventually seeking more formal education in linguistics under the tutelage of Edward Sapir (1884–1939) at the University of Michigan. Under Sapir's mentoring, Pike was led to certain theoretical axioms and practical insights, all motivated by the premise that language and communication can only be fruitfully studied in the context of lived human behavior. This conviction has roots both in Sapir's own anthropological orientation and in Pike's concern to solve the practical challenges of Bible translation within primarily oral cultures.

In his earliest work and publications, ca. 1937–1942, Pike had focused on phonetics, attempting to assist translators associated with the Summer Institute of Linguistics. Their projects entailed the daunting task of understanding and describing phonology, morphology, and syntax among preliterate peoples whose languages had yet to be codified – lacking any guide to sound, lexicon, or grammar by which linguists could successfully enter their language community and attempt skillful translation of Biblical texts.

While devising practical tools of inquiry for identifying and charting similarities and differences in such target languages, Pike intuited that the resolution of translators' challenges lay both beyond the sentence in discourse and beyond discourse itself in the sociocultural frameworks in which language is used. Pike and his colleagues thus began to formulate tagmemics as a linguistics-cum-anthropology-cum-rhetoric based upon the centrality of language use to the building and preservation of human community, personal identity, and social order.

In 1948, Kenneth L. Pike began in earnest his search for a syntactical counterpart to the phonological and morphological terms 'phoneme' and 'morpheme' – a concept at the sentence level or above which could function as a key identifying unit in the same way that these well-established terms had functioned. The pursuit of what came to be known as the tagmeme resulted in Pike's seminal work of three volumes, *Language in relation to a unified theory of the structure of human behavior* (1954–1967). This expansive work articulates the heart of tagmemic theory, whose axioms foreground the epistemological role of culture and behavior at both the macro and micro levels of human community and language.

For Pike, and other prominent tagmemicists such as Robert Longacre, Alton Becker, and Linda Kay Jones, this means that linguistics must eschew formalisms and abstractions that result in purely mechanical or mathematical models of language as

'systems.' Pike referred to this tendency in late 20th-century language study as the fallacy of 'autonomous linguistics,' whose inquiries typically began with presuppositions and ended with propositions that sidestepped the quite essential and meaningful linkage between linguistic inquiry and the way human beings experience the world through the mediation of language. The dominance of transformational/generative linguistics, with its conceptions of competence and grammaticality, has frequently been cited as an exemplar of this unwarranted stance in tagmemic literature.

The impetus for this expansion of tagmemic theory beyond the usual limits of linguistic work was for Pike a nagging epistemological question: how is it that we can recognize persons, ideas, objects without knowing everything about them? As Pike explained colloquially, tagmemic theory staked its claims on the belief that essential to the description of human behavior as we live it must be the ability to recognize a friend even though she has just had Weetabix for breakfast, had restyled her hair, and replaced her automobile with another. What is it about a 'unit,' i.e., any sentence, person, event, situation, object, or concept that allows one to recognize and describe it with tolerable adequacy? As he pursued the implications of his questions further, Pike could no longer treat language as *sui generis*, an autonomous phenomenon that could be studied in isolation from other, nonlinguistic human behavior.

Among the most important axioms Pike offered fledgling tagmemicists was the principle that all language users inevitably view the world in repeatable units, but choose to focus upon them as particles (discrete bits), waves (merging of units and overlapping borders that change over time), or fields (as points in a set of relationships). Pike posited that each of these perspectives may and must come into play in a discourser's understanding and are not to be misunderstood as mutually exclusive. But, each perspective has its limitations as well.

An exclusively particle view of the world may yield nothing but discreteness: unconnected, decontextualized, randomized bits of experience; an exclusively wave view may yield nothing but unstable, ever-shifting strings and combinations of experience that resist articulation and registry; an exclusively field perspective may yield nothing but a mere scaffolding of relational abstractions that bear no substantive, tangible connection to the components of language or life that otherwise orient and order our perceptions and experience.

Pike further argued that every unit of thought or behavior to be well described must be characterized in these three ways: (a) how it differs from everything else in its class; (b) what its range of variability is, i.e., how much it can change and still be itself; and (c) what range of contexts can appropriately contain it, i.e., its distribution among other systems. Within tagmemics, any unit of human experience can (and ultimately **must**) be described through this ultimately trimodal structure.

Perhaps the most influential, and potentially long-enduring, concept invented by Pike is his evocation of the distinction (and the complementarity) between emic and etic viewpoints. Pike coined the terms from the endings of the words, phon**emic** and phon**etic**. The emic view is the perspective of the insider, the native, and is concerned with the contrastive, patterned system within a universe of discourse – its subtleties, its secrets; the emic view is intuitive to the person who possesses it. The etic view of a unit, by contrast, is the perspective of the outsider who looks for universals and generalizations – its predictabilities and linear surface features; the etic view assembles 'facts' without, perhaps, the ability to discern their relevance or, indeed, their priority in a system. The emic view is the view we expect from a participant within a system; the etic view is the view we expect of the alien observer. Both vantage points yield valuable data, but the etic must derive its authority to speak knowledgeably from interaction, even mastery, of the emic.

The overriding goal of any tagmemic inquiry is thus this movement from an etic and toward an increasingly emic understanding of language, text, person, or experience. Emicity and Eticity are thus considered as paradigmatic experiences within the human community and help define a range of human communication successes and challenges.

Eticity comprises the exterior, the detached, reality-as-appearance, founded upon outsider objectivity. Initial etic inquiry typically yields particles whose wave or field relationships (i.e., situatedness) to other particles are undetected, indistinct, or ambiguous and which must be identified before progress can be made toward emic understanding.

Emicity comprises the deeper, reality-as-experience, founded upon insider subjectivity. Etic inquiry, informed by incrementally more accurate and comprehensive account of particles as experienced within wave/field relationships by insiders in a language community, yields ever closer approximation of the community's meaning.

Tagmemics *qua* linguistics is ultimately a theory of discourse founded upon certain axioms about human behavior and language use that foreground the situatedness of all communication and the necessity of viewing every act of discourse as a form-meaning

composite inseparable from communicators, their audiences, and the varied worlds they may construct and inhabit through the use of language. Tagmemics is unique among 20th-century language theories in its preference for identifying universals and in its assertion that its axioms hold true for all of human behavior. It therefore offers insights not only into linguistics, but also into the epistemology of literacy as such, and also into the complexities of human psychology and anthropology.

Like 19th-century French linguist, Ferdinand de Saussure, Pike's rejected the positivism of his day and asserted that language study required not only a science but also an anthropology. At times, tagmemics indeed seems almost entirely an anthropological endeavor, its linguistics performed in the service of understanding better the human community and its varied behaviors.

The continuing influence and impact of tagmemics is to be found in contemporary rhetorical theory, particularly in the United States, where it has been employed to facilitate the acquisition of writing skills, and to provide writing instructors with a comprehensive means of teaching style, audience, argument, and exposition with a greater sensitivity to the situatedness of communication. Pike's theories came to the attention of his University of Michigan colleagues Richard Young and Alton Becker in the 1960s, and together they began the task of harvesting Pike's insights for a 'modern theory of rhetoric,' a theory most fully articulated in their 1970 textbook, *Rhetoric: discovery and change*. Seeking to free rhetoric and writing instruction from a moribund 'current-traditional' model, the authors' broad purpose was to restore invention to its proper place at the heart of practical rhetoric and to reconceive writing as a discovery, i.e., 'problem-solving' process that could be assisted by the systematic heuristic tools Pike developed for tagmemic theory.

From the tagmemic point of view, every rhetor's task is inevitably analogous to the kinds of challenges 'alien' translators in a new cultural environment encounter: locating a point of entry into a particular language ambiguity, problem, or challenge that will provide a true bridge for nonthreatening exchange and that, therefore, might make possible meaningful change. Thus, in tagmemic terms, a rhetorical task involves deliberately compensating for a default etic or outsider's perspective on data under consideration, and employing heuristics that assist a communicator in approximating an emic or insider's perspective conducive to reaching the projected audience.

As a rhetorical theory, tagmemics has faced opposition to its assertion that its axioms hold true not only for language inquiry but for all of human behavior. Nevertheless, tagmemic linguists and rhetoricians continue to investigate and pursue inquiries that illuminate the taxonomic, epistemic, and heuristic functions of language in human discourse toward the project of building an ever-more comprehensive theory of human behavior.

Tahitian

P Geraghty, University of the South Pacific, Suva, Fiji

© 2006 Elsevier Ltd. All rights reserved.

Tahitian belongs to the Eastern Polynesian branch of the Oceanic subgroup of the Austronesian language family. Its nearest relatives are other Central Eastern Polynesian languages, such as Tuamotuan, Marquesan, and Cook Islands Maori.

Until the early 19th century, Tahitian was spoken by the entire population of the Society Islands, and it remained the main language for most of that century. Annexation by France (in 1880) and educational and social policies have contributed to the decline of Tahitian, particularly in the capital, Pape'ete. At the same time, Tahitian has become the lingua franca of the Marquesas, Tuamotus, Austral Islands, and other parts of French Polynesia, at the expense of their respective indigenous languages, and it is now estimated to have 150 000 speakers, including some 5000 residents of New Caledonia.

Tahitian has been an official language of French Polynesia, along with French, since 1978, but more *de jure* than *de facto*. It is taught in a small way up to university level. There is a substantial amount of Tahitian language radio and television programming, but no newspaper. The recent (2004) election of a government committed to more independence from France may bring about changes in the use and status of Tahitian.

Tahitian had no traditional written form and was first recorded by 18th-century explorers such as Bougainville and Cook. The latter was responsible for introducing into English the loanwords *taboo* and *tattoo*, from Tahitian *tapu* and *tatau*. A Roman-based alphabet was devised by English-speaking missionaries in 1815 and has remained in use relatively unchanged. Reliable reference works are currently available only in French.

An unusual feature of Tahitian was the custom of 'pi'i,' by which everyday words that constituted parts of chiefs' names were considered taboo, and in many cases the change became permanent. Tahitian is also unique among Pacific languages in having an academy (Fare Vana'a), founded in 1974, that aims to standardize, develop, and promote the language.

The phoneme inventory of Tahitian consists of nine consonants (f, h, m, n, p, r, t, v, and glottal stop) and 10 vowels (a, e, i, o, u, ā, ē, ī, ō, ū). There are no consonant clusters, and syllables are open. In writing, vowel length and glottal stop have often not been marked systematically. Some modern writers and publishers use a macron to indicate a long vowel and an apostrophe to indicate the glottal stop, as recommended by the Fare Vana'a.

There is very little morphophonemics, and most grammatical functions are performed by affixation or the use of pre- and postposed particles. Pronouns distinguish four persons (including first-person inclusive and exclusive) and three numbers (singular, dual, and plural). There are two categories of possession, depending largely on whether or not the possessor has control over the fact of possession. In noun phrases, the order is head + attribute. The basic word order is VSO:

'ua	tai'o	'oia	i	te	puta	rahi
ASP	read	he	OBJ	the	book	big

'he read the big book'

Tai Languages

D A Smyth, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Geographical Location and Number of Speakers

Tai languages are spoken by over 70 000 000 people across a wide area of Asia that extends from Vietnam in the east to India in the west. The most important member of the family is Thai, the national language of Thailand, which accounts for approximately two-thirds of all Tai speakers. The second highest national concentration is in China, where there are an estimated 15 000 000 speakers, mainly in the southwest. Smaller Tai-speaking populations live in northern Vietnam, Laos, Burma, and northern India.

The Tai language family comprises three branches: southwestern, central, and northern. The southwestern group extends over the widest geographical area and includes the national languages of Thailand and Laos, plus Shan and Khün (spoken in northern Burma); Lü (China-Burma border); Khamti (Burma-India border); and Black Tai (Tai Dam), White Tai (Tai Dón), and Red Tai (Tai Daeng) (Laos-Vietnam border). The central and northern branches are geographically more homogeneous, languages from both groups being spoken in both northern Vietnam and southern China. Central Tai includes Tho (Tày), Longzhou, and Nung, while Northern Tai includes Wu-ming (Northern Zhuang), Yoi (Dioi), and the Bouyei (Pu-yi) languages of China.

Wider Affiliations

Certain lexical and grammatical similarities between the Tai and Chinese languages led linguists in the 19th century to assume that the two groups were related, and until the 1940s this was the widely accepted view. Since then, however, most authorities have come to believe that there is no such genetic link and that any similarities are due to borrowings. The wider affiliation of Tai languages has been the subject of considerable scholarly debate. In 1942, Paul Benedict first linked Tai languages to a small group of languages spoken on the island of Hainan and in southwestern China, for which he coined the term 'Kadai'. Whereas the Tai-Kadai link is, today, accepted by many – but not all – linguists, Benedict's attempt to relate Tai-Kadai languages to the polysyllabic, nontonal, Austronesian (or Malayo-Polynesian) languages of the South Pacific, under the term 'Austro-Tai,' has proved more controversial.

History

Researchers on comparative Tai dialects estimate that the parent language, Proto-Tai, dates back approximately 2000 years. Speakers of this language were once thought to have originated in China and migrated southward, but today the border area between Vietnam and China's Guangxi province is regarded as a more likely origin. From the 8th century A.D., Tai speakers began to migrate westward and southwestward, gradually driving a wedge between the Mon-Khmer speaking peoples then dwelling in what is now Thailand. Around the 11th century, all Tai languages were affected by the Great Tone Split. Essentially, this had the effect of creating additional tones while reducing the number of initial consonant sounds. The effects of this can be seen in a number of Tai writing systems; in Thai, for example, it accounts for the fact that a single tone mark can represent two distinct tones.

Typological Characteristics

The Tai languages are noninflected tonal languages with a basic monosyllabic lexicon. Among the different branches, a single lexical item will often show differences in the initial consonant, vowel, or tone; thus, the word for 'six' is *hok* in several southwestern Tai languages, but is *sok*, *rok*, *lok*, or *huk* in the central and northern branches, depending on the language. Even closely related languages within the same branch are frequently mutually unintelligible because of differences in phonology and certain basic vocabulary items.

The word order in most Tai languages is subject-verb-object, with adjectives following nouns. In Khamti, however, the order is subject-object-verb, probably due to the influence of neighboring languages from other families. Geographical location has also influenced the source of loan words; Tai languages spoken in Vietnam and China have borrowed from Chinese, and members from the southwestern branch have drawn lexical items from Sanskrit and Pali.

The writing systems have been similarly influenced; some central and northern Tai languages are written in Chinese characters, whereas southwestern Tai languages are written in alphabetic scripts that can ultimately be traced back to a south Indian origin. Many Tai languages, however, have no writing system and, with small numbers of speakers and little cultural prestige attached to them, they are in serious danger of becoming extinct.

Taiwan: Language Situation

J DeChicchis, Kwansei Gakuin University, Sanda, Japan

© 2006 J DeChicchis. Published by Elsevier Ltd. All rights reserved.

Events of the past century have dramatically changed the language situation in the Chinese province Taiwan, a truly multilingual country of multilingual speakers. Having begun the 20th century as a territory of Japan, Taiwan came under Chinese suzerainty by mid-century, and it continues to be the seat of government for the offshore Republic of China 中華民國 (ROC), which is now renewing commitments in support of minority languages. History attests that four language families have enjoyed their moments of dominance in this island territory, and these same four families are represented today. Some writers use the word 'Taiwanese' to refer to one of the languages of Taiwan; however, this usage is uninformed at best and chauvinistic at worst.

Austronesian languages have been spoken throughout the big island, Formosa, and on various smaller islands since prehistoric times. Approximately two percent of the current Taiwanese population speaks these autochthonous languages, especially in villages of the central and eastern mountains of Formosa; some are robust languages of daily colloquial use, while others are merely ritual languages. By subgroup, Atayalic languages are spoken in highland villages of Ilan and surrounding counties, Tsouic languages are spoken in villages stretching from the hills above Taitung and along the Pingtung-Kaohsiung border northward to southern Nantou county, and Paiwanic languages, which are the most widespread, are spoken throughout the south, in the central highlands, and along the east coast south of Hualien. The ROC officially recognizes 11 autochthonous Austronesian ethnic groups, and their official roman-script names are used here, although many alternate names (in roman, Chinese, and Japanese scripts) have been used. Of these 11, Thao and Kavalan (both Paiwanic) are being maintained in ritual contexts but are no longer colloquial languages of daily usage. The other officially recognized autochthonous languages are Atayal (Atayalic); Paiwan, Amis, Bunun, Pyuma, Saisiyat (Paiwanic); Tsou, Rukai (Tsouic); and Yami (Bashiic). Only Yami, which is spoken by the Tao people primarily on Orchid Island, is not a Formosan language proper; it is more closely related to the languages of the northern Philippines. Taroko (also called Truku or Sediq) is often said to be a separate Atayalic language, but sometimes it is described as a dialect of Atayal; the official recognition of Taroko is somewhat ambiguous. Fieldworkers in Taiwan have identified other Austronesian languages and dialects (e.g., Pazeh), but all are described as moribund or nearly extinct. The ROC has recently implemented affirmative-action policies for students who speak Austronesian mother tongues.

Some writers use the word 'Taiwanese' to refer to one of the languages of Taiwan; however, this usage is uninformed at best and chauvinistic at worst.

Austronesian languages have been spoken throughout the big island, Formosa, and on various smaller islands since prehistoric times. Approximately two percent of the current Taiwanese population speaks these autochthonous languages, especially in villages of the central and eastern mountains of Formosa; some are robust languages of daily colloquial use, while others are merely ritual languages. By subgroup, Atayalic languages are spoken in highland villages of Ilan and surrounding counties, Tsouic languages are spoken in villages stretching from the hills above Taitung and along the Pingtung-Kaohsiung border northward to southern Nantou county, and Paiwanic languages, which are the most widespread, are spoken throughout the south, in the central highlands, and along the east coast south of Hualien. The ROC officially recognizes 11 autochthonous Austronesian ethnic groups, and their official roman-script names are used here, although many alternate names (in roman, Chinese, and Japanese scripts) have been used. Of these 11, Thao and Kavalan (both Paiwanic) are being maintained in ritual contexts but are no longer colloquial languages of daily usage. The other officially recognized autochthonous languages are Atayal (Atayalic); Paiwan, Amis, Bunun, Pyuma, Saisiyat (Paiwanic); Tsou, Rukai (Tsouic); and Yami (Bashiic). Only Yami, which is spoken by the Tao people primarily on Orchid Island, is not a Formosan language proper; it is more closely related to the languages of the northern Philippines. Taroko (also called Truku or Sediq) is often said to be a separate Atayalic language, but sometimes it is described as a dialect of Atayal; the official recognition of Taroko is somewhat ambiguous. Fieldworkers in Taiwan have identified other Austronesian languages and dialects (e.g., Pazeh), but all are described as moribund or nearly extinct. The ROC has recently implemented affirmative-action policies for students who speak Austronesian mother tongues.

The ROC interprets archaeological evidence as suggestive of ancient Sinitic language use on Formosa; however, historical records indicate that today's Min Nan Chinese 閩南語 (autonymically, Bân-lâm-gú) and Hakka Chinese 客家語 speakers are descended from 17th-century immigrants from the Chinese mainland. Min Nan speakers have been in the Pescadores (Penghu) Islands 澎湖群島 at least as long. Min Nan Chinese (locally known as Holo or Hoklo but also known as Amoy, Hokkien, or Fujianese language) is the mother tongue of two-thirds of Taiwan's population, and many Taiwanese speak it as a second language. Beyond Taiwan Province, Min Nan is the indigenous and dominant language in the Kinmen (Quemoy) 金門列島, Wuchiu 烏坵嶼 and Matsu 馬祖列島 island groups, which, though politically part of the mainland Fujian province, are also administered by the ROC. An important lingua franca, Min Nan is the second most common language in terrestrial television broadcasts, and the Amoy Bible is popular among certain Christians. On the other hand, Hakka Chinese is strictly an emblematic language of the Hakka ethnic group that is used in their villages on Formosa. Many ethnic Hakka (by some estimates, about half) have lost the ability to speak Hakka, especially in urban areas, but a Hakka language revival is currently underway, and Hakka-language radio programs enjoy increasing popularity. In contrast, Mandarin Chinese (locally Guoyu or Kuoyü 國語 but also known as Huayu 華語 or Putonghua 普通话), which is historically the third Sinitic language of Taiwan, became a language of significant immigration in 1949, when the ROC made Taipei its government seat. Before that time, very few families in Taiwan spoke Mandarin at home, even though Mandarin was, as it is now, the official language of the ROC government and the language of school instruction. However, in the years since the ROC's removal to Taiwan, aggressive language standardization, effective education, and centrally controlled mass media have resulted in more than 95% of Taiwanese becoming fluent speakers of Mandarin, as either a first or second language. Mandarin is the overwhelmingly dominant language of television, and, with the exception of small children and some older people, it is understood throughout Taiwan. The ROC continues the traditional writing of Mandarin, in contrast with the use of simplified characters in the People's Republic of China 中华人民共和国 (PRC). Taiwan publishers also continue the use of the Zhuyin Fuhao 注音符號, also known as bopomofo ㄅㄆㄇㄈ, the Chinese system of phonetic writing developed in the early 20th century. Primarily used for teaching proper pronunciation to Mandarin-speaking children, the Zhuyin characters have also been used to write Austronesian languages, most notably in church hymnals and popular guide books.

A third language family is represented by Japanese, the official language of Taiwan from 1895 until 1945. Taipei University was one of the original imperial universities of Japan, and educated Taiwanese became fluent Japanese speakers. This enculturation was so effective that Japan permitted many Taiwanese to retain their Japanese citizenship after the war. Thousands of older Taiwanese are still capable of speaking Japanese. Business and cultural ties with Japan remain strong. Japanese is a popular foreign language of study among young people, and both young and old enjoy Japanese language television and films.

Indo-European languages and roman script orthographies have been in Taiwan since the Portuguese named the big island Ihla Formosa. A Spanish outpost was also established in the north. The Dutch colonized western Formosa in the 17th century, establishing schools and devising Sinckan writing, a roman script, for writing some of the Austronesian languages spoken near Tainan. However, the Dutch colony eventually failed, and no European colonial language ever became permanently established. In the 19th century, English-speaking missionaries introduced the popular Peh-oe-ji roman script, in which Taiwan's first newspaper was published, in Min Nan Chinese, from 1885 to 1970. Min-Nan-language Bibles written in Peh-oe-ji are currently available. English has become the territory's most popular foreign language, and strong political and commercial ties with the United States reinforce the current use of English.

A typical Taiwanese, depending on her or his age, ethnicity, education, and social network, speaks a selection of the above-mentioned languages. Other languages spoken in Taiwan tend to be associated with resident aliens. One exception is Arabic, which arrived with the large group of Islamic Chinese who arrived in 1949. The deaf of Taiwan use an indigenous sign language that is distinct from the well known American, Chinese, and Japanese standards.

Tajik Persian

J R Perry, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Tajik Persian (self-designation (*zabon-i*) *forsi-i tojikī*; also called Tajik, Tajiki, Tojikī, and Tadzhik) is the variety of Persian used in Central Asia (*see* **Persian, Modern; Persian, Old**). Since the 1920s, Tajik has been fostered as the national literary language of the Tajik Soviet Socialist Republic (since 1991, the Republic of Tajikistan). It is also spoken in parts of Uzbekistan (notably the cities of Bukhara and Samarkand) and is the vernacular of the Bukharan Jews. It is the common written language and contact vernacular in the mountain region of Badakhshan, where people speak a variety of very different Iranian languages (*see* **Iranian Languages**). The so-called Tajiks of southwestern Xinjiang in China speak Sarikoli and Wakhi, not Persian. Tajik has been written in a modified Cyrillic script since 1940. Speakers number at least 5 million.

History

Persian spread to Central Asia from its home on the Iranian plateau during the 8th century C.E., as the language of Iranian converts attached to the invading Arab Muslim armies. At the autonomous Samanid court of Bukhara (9th–10th centuries), Persian was patronized as the literary language and displaced the indigenous Iranian language, Sogdian (a descendent of which, Yaghnobi, survives in the mountains of western Tajikistan). As a written language, Persian of Central Asia was hardly distinguishable from Classical Persian of Iran, Afghanistan, and India up until the early 20th century. However, invasions and settlement by Turkic peoples (most recently, the Uzbeks) in the Oxus basin and its foothills interrupted the dialect continuum; spoken Persian of Central Asia evolved independently of Persian of Iran, and northern dialects in particular were strongly influenced by Turkish speech. Persian speakers of the region came to be called Tajiks (from a Middle Persian word meaning 'Arab'), in contradistinction to Turks.

After the Russian revolution, in accordance with Soviet nationalities policy, an ethnic Tajik republic was established and a literary language called 'Tajik' was engineered on a vernacular base close to the Uzbekized spoken Persian of Bukhara and Samarkand (these Tajik cultural centers, ironically, were incorporated in the Uzbek Soviet Socialist Republic). During the period ~1948–1988, Tajik lost much of its prestige, vocabulary, and domain of use, to Russian. With *perestroika* and *glasnost'* came a revival and re-Persianization of the national language, which continues (at a slower rate) in post-Soviet Tajikistan; policies include the replacement of Russian vocabulary by Persian (both native coinages and loans from Persian of Iran), and teaching of the Perso–Arabic writing system in schools.

Tajik is fundamentally Persian in grammar and core vocabulary, though generally closer to the spoken Persian of Afghanistan (e.g., Kaboli dialect) than to Standard Persian of Iran. The following descriptions highlight features that differ substantially from Standard Persian, in particular the elements of convergence with Turkic types characteristic of the bulk of Tajik literature in the Soviet period.

Phonology and Orthography

The Tajik sound system is shared almost entirely with that of Uzbek. Its Cyrillic orthography is basically Russian specific, and is illustrated here only when it involves modified or ambiguous characters.

The consonant inventory differs from that of Persian only in two features: [q] <ҚҚ> and [ɣ] <ғ> are distinct phonemes (they have collapsed in the Persian of Iran), and labiodental [v] tends toward bilabial [*β*] or [w] in the environment of rounded vowels. The affricates [tʃ] <ч> and [dʒ] <ҷ> will

Tajik Persian (self-designation (*zabon-i*) *forsi-i tojikī*; also called Tajik, Tajiki, Tojikī, and Tadzhik) is the variety of Persian used in Central Asia (*see* **Persian, Modern; Persian, Old**). Since the 1920s, Tajik has been fostered as the national literary language of the Tajik Soviet Socialist Republic (since 1991, the Republic of Tajikistan). It is also spoken in parts of Uzbekistan (notably the cities of Bukhara and Samarkand) and is the vernacular of the Bukharan Jews. It is the common written language and contact vernacular in the mountain region of Badakhshan, where people speak a variety of very different Iranian languages (*see* **Iranian Languages**). The so-called Tajiks of southwestern Xinjiang in China speak Sarikoli and Wakhi, not Persian. Tajik has been written in a modified Cyrillic script since 1940. Speakers number at least 5 million.

History

Persian spread to Central Asia from its home on the Iranian plateau during the 8th century C.E., as the language of Iranian converts attached to the invading Arab Muslim armies. At the autonomous Samanid court of Bukhara (9th–10th centuries), Persian was patronized as the literary language and displaced the indigenous Iranian language, Sogdian (a descendent of which, Yaghnobi, survives in the mountains of western Tajikistan). As a written language, Persian of Central Asia was hardly distinguishable from Classical Persian of Iran, Afghanistan, and India up until the early 20th century. However, invasions and settlement by Turkic peoples (most recently, the Uzbeks) in the Oxus basin and its foothills interrupted the dialect continuum; spoken Persian of Central Asia evolved independently of Persian of Iran, and northern dialects in particular were strongly influenced by Turkish speech. Persian speakers of the region came to be called Tajiks (from a Middle Persian word meaning 'Arab'), in contradistinction to Turks.

After the Russian revolution, in accordance with Soviet nationalities policy, an ethnic Tajik republic was established and a literary language called 'Tajik' was engineered on a vernacular base close to the Uzbekized spoken Persian of Bukhara and Samarkand (these Tajik cultural centers, ironically, were incorporated in the Uzbek Soviet Socialist Republic). During the period ~1948–1988, Tajik lost much of its prestige, vocabulary, and domain of use, to Russian. With *perestroika* and *glasnost'* came a revival and re-Persianization of the national language, which continues (at a slower rate) in post-Soviet Tajikistan; policies include the replacement of Russian vocabulary by Persian (both native coinages and loans from Persian of Iran), and teaching of the Perso–Arabic writing system in schools.

Tajik is fundamentally Persian in grammar and core vocabulary, though generally closer to the spoken Persian of Afghanistan (e.g., Kaboli dialect) than to Standard Persian of Iran. The following descriptions highlight features that differ substantially from Standard Persian, in particular the elements of convergence with Turkic types characteristic of the bulk of Tajik literature in the Soviet period.

Phonology and Orthography

The Tajik sound system is shared almost entirely with that of Uzbek. Its Cyrillic orthography is basically Russian specific, and is illustrated here only when it involves modified or ambiguous characters.

The consonant inventory differs from that of Persian only in two features: [q] <ҚҚ> and [ɣ] <ғ> are distinct phonemes (they have collapsed in the Persian of Iran), and labiodental [v] tends toward bilabial [*β*] or [w] in the environment of rounded vowels. The affricates [tʃ] <ч> and [dʒ] <ҷ> will

Figure 1 Tajik vowels.

be transliterated as *č* and *j*, [j] <й> will be transliterated as *y*, and <ҳ> [h] will be transliterated as *h*.

The six-vowel system has diverged considerably from Standard Persian (see **Figure 1**). Length has been neutralized in most dialects (including literary Tajik) and replaced by a contrast between 'stable' [e, ы, ɒ] and 'unstable' vowels [i, u, a]. In Cyrillic, [ū] is written ӯ (transliterated *ū*); *i*, written as и, has a variant ӣ (transliterated *ī*). These accents do not represent length: *ū* shows a different quality from *u*, and *ī* is used for *i* in word-final position to distinguish a (stressed) morphological syllable from the (unstressed) enclitic of *izofat* (see later, Morphology and Noun Phrase Syntax). The vowel [e] represents early New Persian [eː]; [ы], sounding between [u] and [y], represents early New Persian [oː] and is shared with Uzbek, in which it corresponds to Turkic [y] or [ø]. The vowel [ɒ] <о> is a rounded form of Standard Persian [ɑ]. The three 'unstable' vowels correspond to the 'short' vowels of Persian, but [i] and [u] additionally represent the corresponding 'long' vowels.

Examples of modern correspondences in Tajik and Persian, respectively, are *kitob*, *ketâb* 'book'; *imrūz*, *emruz* 'today'; *Bedil*, *Bidel* 'name of a poet'; *na-budem*, *nabudim* 'we were not'; and *šuda*, *šode* 'having become' (the final [a] is not raised in Tajik). The yotated letters ё, ю, and я represent the syllables *yo*, *yu*, and *ya*; Cyrillic е stands for *e* after a consonant, *ye* initially or after a vowel.

Morphology and Noun Phrase Syntax

There is no grammatical gender in Tajik and only a limited distinction between humans and nonhumans in the plural suffixes *-ho* (any noun) and *-on* (humans and higher animals), and in third-person singular personal pronouns, as follows: *vay* (general), *ū* (literary), *in* (dialect) 'he, she'; *on* (literary), *in*, [*h*]*amin* (colloquial), *vay* (dialect) 'it'; *onho* (general), *in*[*h*]*o* (colloquial), *vay*[*h*]*o* (dialect) 'they' (all classes). The deferential pronoun *ešon* (cf. Persian *išân*) 'he, she' (lit. 'they') has been replaced in Tajik by *in kas* 'this person.' Plural pronouns, which may refer deprecatingly or deferentially to a singular (SG) person, can add plural (PL) suffixes as 'explicit plurals': *mo*/*mo-yon*, *mo-ho*, *mo-hon* 'we, I/we'; *šumo*/*šumo-yon*, *šumo-ho* 'you' (SG)/'you' (PL; see later, discussion of verb endings).

The basic noun phrases (NPs) are the nominal *izofat* (IZ; Persian *ezâfe*), e.g., *qišloq-i Alijon* 'Alijon's village' (village-of Alijon), and adjectival *izofat*, e.g., *qišloq-i kalon* 'the big village' (village-big); in both types, the head is linked to a following modifier by the enclitic *-i*. There are no articles; an indefinite NP may be marked by the numeral *yak* 'one' and/or the 'specific' (SPEC) enclitic *-e*; a definite NP (supplying old information) is distinguished only in the object (OBJ) position, by the enclitic *-ro*. A direct object that is familiar to the speaker, but not to the listener, is marked by both enclitics, as shown in the following examples:

pisar-ro did-am
boy-OBJ see.PAST–1SG
'I saw the boy.'

yak pisar(-e) did-em
one boy(-SPEC) see.past–1PL
'We saw a boy/some boy or other.'

pisar-e-ro did-em
boy-SPEC-OBJ see.PAST–1PL
'We saw a (certain) boy.'

Other case relations are expressed through prepositions (including *bar* 'upon' and *be* 'without,' no longer active in Persian), postpositions, and circumpositions (inflectional suffix *izofat*):

qayčī kati noxun girift-am
scissors with nail take.PAST–1SG
'I cut my nails with scissors.'

az ibtido-i paxta-činī in-taraf
from start-IZ cotton-picking this-side
'Since the start of cotton-picking.'

A superlative as modifier may precede the head noun (as in Persian), or may follow it:

šahr-i kalon-tarin-i tojikiston
city-IZ larg-est-IZ Tajikistan
'The largest city of/in T.'

Nouns take the singular after a number. A classifier may intervene, most commonly the enclitic *-ta* or *-to* 'fold, item,' as in *yak-ta zan* 'one woman' and *sad-to kurta* 'a hundred shirts' (or *yak-sad kurta* 'one hundred shirts').

The simplex tenses of Tajik verbs are the same as in Persian, except for the vowel of the present/imperfect prefix, and of the first-person plural and second-person plural personal endings, as in *me-kun-em* 'we do' and *kard-ed* 'you did.' The second-person plural form may also add an 'explicit plural' supplement (cf. preceding discussion of pronouns) derived from the pronominal

enclitic *-ton*, as in *šin-eton*, *rafiq-on* 'sit down, friends' (*ŝined + ton*). In compound tenses and moods, Tajik verbal morphology has expanded beyond that of Persian. Three progressive tenses are formed on the past participle of a desemanticized *istodan* 'to stand' (in the following examples, verb glosses in bold type indicate an apparent 'past participle' (PP) not forming part of a tense, which is used extensively as a nonfinite verb form (gerund) in verbal conjuncts):

bača-ho ovoz xonda istoda-and
child-PL song **sing** stand.PP-be.3PL
'The children are singing' (present progressive).

An epistemic mode of the indicative (called 'nonwitnessed,' or 'evidential') also has three tenses. Thus, the regular perfect may function as an evidential present:

vay sayohat-ba rafta-ast
he journey-on go.PP-be.3SG
'He went/has gone on a trip (– so I surmise/am told).'

Note here the Persian preposition as a Turkish-style postposition. This mode also includes progressive tenses:

šumo yak asar-i nav navišta istoda-buda-ed
you one work-IZ new **write** stand.PP-be.PP–2PL
'You've been writing a new work (– so I gather/see).'

Here the form expresses a mirative, i.e., the appreciation of a fact not previously known.

The conjectural mood uses an augmented (AUG) form of the past participle in *-agī* to form tenses expressing a probable situation or event (IMPERF, imperfect):

yagon kor-i ganda karda-gi-st
some deed-IZ bad do.PP-AUG-be.3SG
'He must have done something bad' (past).

dast-u rū me-šusta-gi-st-ed
hand-and face IMPERF-wash-AUG-be–2PL
'(I imagine) you'll want to freshen up' (present/future).

The future participle (infinitive + adjectival formative *-ī*) is used in a quasifuture tense, and adjectivally, much more than in Persian:

xohar-am ba maktab omad-an-ī bud
sister-my to school come-INF-ADJ be.PAST
'My sister was eager to go to school.'

From an intransitive verb, the sense is active, and with a human subject, usually connotes intention. From a transitive verb, the sense may be passive (NEG, negation):

jo-ho-i no-guft-an-ī
place-PL-IZ NEG-say-INF-ADJ
'Unmentionable places; locations not to be divulged.'

The augmented past participle (also of progressive tenses) is extensively used in ways (and positions, i.e., preceding the head) similar to use in Uzbek participles, to express what, in Persian, would often be a relative clause:

gurexta-istoda-gi-ho
flee-stand.PP-AUG-PL
'Those who are/were fleeing; the fugitives.'

ana kitob-i ovarda-gi-am
here book-IZ bring.PP-AUG-my
'Here is the book that I brought.'

duxtar kurta-i me-dūxta-gi-aš-ro
girl shirt-IZ IMPERF-sew.PP-AUG-her-OBJ
ba modar-aš nišon dod
tomother-her sign give.PAST
'The girl showed the shirt that she was/had been sewing to her mother.'

The Lexicon

Nominal and adjectival compounds are formed with suffixes and prefixes, some of them different from (or more productive than) their Persian counterparts. Thus *-nok* denotes something having the quality of the base noun, as in *foida-nok* 'beneficial, profitable' (*foida* 'use, profit') and *sado-nok* 'vowel' (*sado* 'sound, voice'); *ser-* 'sated, full' indicates an abundance of the base noun, as in *ser-gap* 'garrulous' (*gap* 'talk'), and *to-* 'up to, until' produces, e.g., *to-inqilob-ī* 'prerevolutionary' (*inqilob* 'revolution,' *-ī* is the relative adjective formative); this use of the preposition *to* (unknown with Persian *tâ*) is probably calqued on similar use of Russian *do* 'up to, until.' Other Russian calques use Tajik *sar* 'head' by analogy with the Russian prefix *glav-*, as in *sar-muhandis* 'chief engineer' (Russian *glav-inžener*). Most derivatives from Russian loans freely use Tajik Persian formatives, as in *bolševik-ī* 'Bolshevik' (adjective).

Transitivizing denominal verbs and causatives (CAUS) (obtained by infixing *-on-*) are more productive than in Persian, as in, *kollektiv-on-idan* 'to collectivize.' They may also be formed from complex and composite verbs:

papiros dar me-gir-on-ad
cigarette in IMPERF-take-CAUS–3SG
'She lights a cigarette.'

(Compare *dar me-gir-ad* 'it catches fire.') In some complex verbs, the preverbs *dar* and *bar* are attached to the verb stem: *me-dar-o-y-ad* 'he comes in' (cf. Persian *dar mi-â-y-ad*).

Characteristic of Tajik are conjunct verbs (serial verbs), of which the progressive tenses are grammaticalized instances. There are some 18 lexically

established conjunct auxiliaries (corresponding to models in Uzbek) that, in regularly conjugated tenses, furnish adverbial 'modes of action' for the nonfinite participle (semantically, the main verb):

dars-i nav-ro navišta girift-em
lesson-IZ new-OBJ **write** take.PAST–1PL
'We copied down the new lesson' ('take': self-benefactive).

nom-i xud-ro navišta me-dih-am
name-IZ own-OBJ **write** IMPERF-give.PRES–1SG
'I'll jot down my name (for you)' ('give': other-benefactive).

berun-ho-ya toza karda rūfta parto!
outside-PL-OBJ clean **make sweep** throw.IMP
'Sweep all the outside nice and clean!'

The preceding example demonstrates a double conjunct construction: the auxiliary *partoftan* 'to throw (away), toss' adds the sense of thoroughness or completion (*-ya* is a dialect variant of *-ro*, and *toza kardan* 'to clean' is a typical Persian-type composite verb).

Syntax

Verbal conjuncts, mostly of Uzbek inspiration, compete in other ways with the Persian syntax of subordinate clauses introduced by conjunctions; e.g., the favored construction for the modal verb *tavonistan* 'to be able' is as follows:

man rafta (na-)me-tavon-am
I **go** (NEG-)IMPERF-can.PRES–1SG
'I can(not) go.'

Also embedded in the literary language is the nominalization of sentential complements through infinitives, as in the following example:

mo {kujo raft-an-i xud-ro}
we {where go-INF-IZ own-OBJ}
me-don-em
IMPERF-know.PRES–1PL
'We know where we are going' (. . . our going-where).

Uzbekisms in colloquial and northern dialect usage include the question (Q) enclitic *-mi* and possessive NPs, with (dative) *-ro* replacing the *izofat* construction (OBL, oblique):

muallim-a [-ro] pisar-aš raft-mī?
teacher-OBL boy-his go.PAST-Q
'Has the teacher's son left?'

These features were not admitted into literary Tajik, and even some of the accepted Uzbekisms are fading from post-Soviet Tajik writing.

Tajikistan: Language Situation

L Johnson, Mainz University, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Languages

Tajikistan, the smallest republic of Central Asia, bordering Uzbekistan, Kyrgyzstan, Afghanistan, and China, has been an independent state since 1991 and has a population of over 5 million (1989 census: 5 092 603).

Since the 1920s, its national language has been Tajik (Tajik Persian, Tajiki, *zaboni tojik*, *tojikî*). Tajiks constitute more than 60% of the population. Tajik, a variety of Persian (Farsi), but an independent language in the political sense, belongs to the West Iranian group of the Iranian branch of Indo-European. The variety predominantly spoken in Tajikistan is the southern, only moderately Uzbekicized dialect. Almost a million Tajik speakers live in neighboring Uzbekistan; smaller Tajik groups exist in Afghanistan and China.

Turkic-speaking groups make up about one fourth of the population of Tajikistan. The Turkic language of the Uzbeks, who constitute 23.5% of the population, dominates the northern part of the republic, including the Ferghana valley, with the second largest city Khojand (formerly Leninabad). There are also smaller groups of Kirghiz, Kazakhs, Turkmens, Tatars, and Uyghurs. The number of Russians, who made up 7.6 percent of the population in 1989, has now decreased. There are numerous other linguistic minority groups.

Speakers of some Eastern Iranian languages, Yaghnabi (Yagnobi) and Pamir languages, have remained unassimilated by their Persian- or Turkic-speaking neighbors. Badakhstan, Tajikistan's mountainous eastern province, is the home of the Iranian languages of the Pamir group: Shughni (40 000), Wakhi (7000), Yazgulami (Yazgulyam) (4000), and so forth. The speakers of Yaghnabi, who are now scattered, formerly inhabited the high mountain valley of the Yaghnab River.

Language Policy

With the division of Soviet Turkestan in 1929, the Tajiks were officially divided from the Uzbeks, with whom they had much in common. In the Soviet era, they also lost contact with Persian-speakers abroad. The Arabic alphabet was abandoned in favor of a modified Roman alphabet for Tajik. A Cyrillic-based alphabet was introduced in 1940.

The language policy of the 1930s and 1940s led to a situation in which Russian came to dominate public life. The proportion of Russians in Tajikistan grew rapidly, whereas the proportion of Tajiks decreased from 80% to about 50%. The capital Dushanbe (Stalinabad), largely created by Russian immigrants, remained a predominantly non-Tajik city.

The privileged position of Russian in society was increasingly criticized. The reforms of the 1980s enabled the Tajiks to oppose the current language policy and to organize a strong language movement. A language-status law passed in 1989 declared Tajik to be the state language. After Tajikistan's declaration of independence, a new language law was passed (1992) aimed at replacing Russian as the language of government and higher education. The government even allowed some freedom for education and publication in the Pamir languages. There was a strong language movement in favor of sociolinguististic reforms and of reducing the Slavic and Turkic dominance. The plans even included, and still include, a return to the Persian-Arabic writing system in the near future. Though the language reform efforts have lost some strength since then, efforts continue to reduce borrowings of Russian and Uzbek origin in Tajik and to introduce vocabulary from Persian of Iran.

Talk Shows

C Ilie, Örebro University, Örebro, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The talk show is a highly confrontational discursive genre, a widely influential media phenomenon, as well as a politically and morally controversial form of entertainment. Few discursive practices of popular broadcast culture have been more contentious and subject to cultural and scholarly examination in recent years than the talk show, particularly the television talk show.

The very notion of talk show raises issues concerning the boundaries between talk (prototypically dialogical) and show (prototypically monological), between public and private, between collective and personal experience, between expertise and experience, between interpersonal and mass communication, between information and entertainment, between discrete and overlapping identities ('me,' 'you,' 'us,' 'them'). According to Munson (1993), the term 'talk show' combines two different, often contradictory, rhetorical paradigms by associating interpersonal conversation (belonging to the pre-modern oral tradition) with the mass-mediated spectacle (emerging in modernity). As a result, a public-colloquial language (Leech, 1966) has developed, which is modeled in varying ways upon the practices of conversational speech, through a process of 'conversationalization' of public discourse (Fairclough, 1995).

Brief Historical Survey

The talk show is a modern Anglo-Saxon institution that may be seen to echo certain pre-modern sociocultural practices of purposeful conversation. According to Burke (1993: 114–115) 16th century Italy had the academy, a discussion group for intellectuals, with fixed membership and fixed days for meetings. The 17th century saw the emergence of its French counterpart, the *salon*, a semi-formal social occasion organized by a hostess, normally once a week, for a mixture of ladies and men of letters. In England, the equivalent social institutions flourished in the 18th century in the form of the more informal coffee-house, the assembly, and the club.

The origin of talk shows was tracked down by Munson as early as the 1930s when interactive talk radio started to emerge in the United States and listeners were invited to phone in. Two particular formats developed in the 1960s, namely all-talk and all-news radio programs, which were intended as services to the listening community rather than stations in the traditional sense. Since the listeners were potential customers, controversial and sensationalized talk soon developed to attract them. 'Confrontalk' (Hutchby, 1996) became a syndicated television talk genre in the 1960s.

Phil Donahue was the first to adapt the audience participation talk show (also termed "audience discussion program" and "studio debate program") from radio to television in 1967. His show initiated what is known today as daytime talk show or tabloid talk show. This format was consolidated by Oprah Winfrey from 1984 as a sort of modern update of women's service magazines in the late 19th century in that it often tackles women's issues and targets mainly an audience of housewives. American talk shows such as *Oprah Winfrey, Ricki Lake,* and *Montel Williams* have been gradually exported to the U.K., to several European countries, and to most countries in South America. As a result of an increasing decentralization of the media, a transition from debate programs to talk shows occurred in Europe in the 1980s.

Defining Talk Shows

There are three main reasons why it is a very challenging task to define talk shows: they represent rapidly changing hybrid media phenomena, they display intertextuality through overlaps with other mediatized forms of talk, and they endlessly reconstruct themselves by violating and transgressing their own discursive conventions. The talk show displays a hybrid broadcast discourse in which patterns of communicative and social behavior can be associated with more than one discourse type, through overlaps with other mediatized forms of talk, such as interviews, debates, sitcoms, game shows, and quiz shows. To capture its distinctive features it is essential to explore the sociocultural environment and the contextual factors that generated it and that continue to shape it. The latter are principally the television show format, setting, time frame, and goal; the show host's personal profile, agenda, and general orientation; the participants' backgrounds, goals, and their relations.

In talk shows the interpersonal talk is geared to public debate using partly conversational, partly institutional discursive conventions and strategies, which involves blurring the boundaries between traditional dichotomies, such as public vs. private, collective vs. personal experience, expertise vs. experience. This is why the talk show discourse was

labeled quasi-conversational by Gregori-Signes (2000b), and semi-institutional by Ilie (1999, 2001). Talk shows display a certain gradation of discursive features in terms of institutionalization, with conversational features at the informal end of the speech continuum, and institutional features at the formal end. Depending on the personality of the show host, the nature of the topic, the general background and views of the participants, as well as the type of audience, talk show participants combine spontaneous and purposeful talk, non-institutional and institutional roles, non-controlled and host-controlled talk, interlocutor-oriented, message-oriented, and multiple audience-oriented talk (Ilie, 2001).

Characteristic Features of Talk Shows

Characteristically, talk shows bring together, through the mediation of a host, a guest panel (experts and lay participants), a studio audience and occasionally an audience of 'callers.' The following are some of the key features of talk shows:

1. As audience-oriented mediatized events, talk shows target simultaneously a multiple audience made up of the directly addressed audience of interlocutors, the on-looking studio audience, and the overhearing audience of TV-viewers.
2. Both experts and lay people are often present as show guests. Much of the program's focus has to do with the interchange between them.
3. The show host, usually a media personality, is monitoring most of the discussion by stimulating, guiding, and facilitating the participants' roles and contributions to the program (for information exchange, confrontation, and entertainment).
4. Each episode of the program focuses on a particular topic of social, political, or personal concern. Confrontation and conflicting opinions are usually guaranteed by the selection of topics and of participants.
5. Personal experience and common sense have considerable status and increasingly appear as forms of knowledge that are opposed to expertise and to dominant discourses (of power, race, gender, etc.).
6. The discursive strategies of talk shows are: interview, narrative, debate, game, confession, testimony.
7. These programs are usually inexpensive to produce, particularly because they are not part of prime-time broadcasting.
8. Most programs are either broadcast live or recorded in real time with little editing.

A systematic account has been given by Ilie (2001) of the correlation between the discursive and linguistic features that single out talk shows as a broadcaster-controlled, host-monitored, participant-shaped, and audience-evaluated speech event. The institutional prerequisites of the talk show underpin its situational and discursive constraints. The situational constraints concern talk-related restrictions, such as time restrictions and agenda restrictions, speaker-selection restrictions and turn-taking restrictions. The discursive constraints are reflected in talk-framing patterns, such as the predetermined topic schedule, conventionalized beginnings and closings, as well as recurrent breaks. The semi-institutional aspect of talk shows is manifested in less predictable topic and subtopic shifts, interruptions, unprompted participant interventions, audience-oriented repetitions and audience-oriented questions.

The hybrid nature of the talk show can profitably be examined by adopting a comparative perspective since they exhibit both conversational features (belonging to non-institutional discourse, such as regular conversation) and institutional features (belonging to institutional discourse, such as news interviews and public debates), as indicated in Table 1. The recurrence and distribution of the two sets of features vary according to the particular framing of each talk show, including the personalities and life-roles of the show guests, the charisma and authority of the show host, and the expectations raised by the particular character of the show in question.

In strictly linguistic terms, talk shows exhibit specific features with regard to the discursive organization of talk, the sequence of adjacency pairs and turns, and the participants' question-asking and question-answering roles. These features pertain partly to conversational, i.e., non-institutional discourse, and partly to institutional discourse, as shown in Table 2; the semi-institutional nature of this double dependency is what characterizes talk show interaction.

Typology of Talk Shows

Five major criteria have been used in varying ways by talk show scholars to identify and distinguish between various talk show formats: (i) discussion topics (from contemporary political issues to social or moral problems); (ii) categories of participants, particularly in terms of social and popularity status (celebrities or ordinary members of the public); (iii) broadcasting time (early morning, daytime, or late night); (iv) organizational and interactional frameworks (staging conventions and seating configurations for show guests and audience); and (v) ethical considerations (the producers' and hosts' moral concerns).

Table 1 Discursive Features of Talk Shows as Semi-institutional Discourse

Conversational features	*Institutional features*
Private setting (pre-filmed scenes in show guests' homes)	Public/institutional setting (TV studio)
Relatively homogeneous form of talk	Non-homogeneous form of talk
Spontaneous talk (less topic-centered)	Purposeful talk (more topic-centered and goal-oriented)
Lower topic control and predictability	Higher topic control and predictability
Communicative and interactional goals	Communicative, interactional, and institutional goals
No particular talk-related restrictions (flexible turn-taking, topic and subtopic shifts)	Particular talk-related restrictions (time-limitation, speaker-selection, and turn-taking design)
Non-institutional/real-life roles (parent, child, etc.)	Institutional roles (panelist, expert, etc.) and non-institutional roles (parent, child, etc.)
Spontaneous role-switching (initiated by the show guests)	Monitored role-switching (controlled by the show host)
Equal participant status	Unequal participant status
Equal speaking rights	Unequal speaking rights
Interlocutor as both addressee and addressor	Multiple audience as addressee (onlooking audience and overhearing audience)
Interlocutor-oriented talk	Message- and multiple audience-oriented talk
Non-hierarchical role-distribution	Hierarchical role-distribution
Symmetrical power relations	Asymmetrical power relations
Relatively weak talk/topic control	Strong talk/topic control

Table 2 Linguistic Features of Talk Shows as Semi-institutional Discourse

Conversational features	*Institutional features*
No particular talk-framing patterns	Particular talk-framing patterns
No particular role-related openings and closings	Role-related openings and closings performed by the show host
Informal introductions of and by the participants	Formal and semi-informal introductions of the participants by the show host
Non-monitored speaker-selection and turn-taking (unplanned interventions)	Monitored speaker-selection and turn-assignment
No explicit metalinguistic patterns for various stages of the interaction (negotiated turn-taking slots, next speaker selection, and topic agenda)	Explicit metalinguistic patterns for various stages of the talk show (monitored turn management, next speaker selection, commercial break announcements)
No deliberate use of performative utterances for institutional goals	Deliberate use of performative utterances for institutional goals
Fairly symmetrical question-asking roles	Asymmetrical question-asking roles
Conversationally framed questions (primarily interlocutor-oriented)	Institutionally framed questions (primarily audience-oriented)
Argumentatively used non-answer eliciting questions (e.g., rhetorical questions)	Evaluatively used non-answer eliciting questions (e.g., rhetorical questions); audience-oriented questions (e.g., expository questions)
Interlocutor-oriented repetitions (self-repetitions, allo-repetitions)	Audience-oriented repetitions (addressee-shifting repetitions, message retargeting repetitions)

According to the first criterion, Krause and Goering (1995) distinguish three categories of talk shows in the United States: the news/political analysis talk show (*Meet the Press*), the entertainment talk show (*The Tonight Show*). and the social issue talk show (*Sally Jesse Raphael*, *Oprah*). By applying the first two criteria, Carbaugh (1988) distinguishes between personality-type and issue-type

talk shows. Other authors, like Charaudeau and Ghiglione (1997), resort mostly to the first criterion to distinguish between monothematic and polythematic talk shows. The third criterion is widely used by scholars to distinguish between early morning talk shows (*Ricki Lake*), daytime talk shows (*Oprah Winfrey, Geraldo Rivera*), and late night talk shows (*David Letterman*). By applying the first three criteria, Haarman (1999: ix) distinguishes three broad categories of talk shows: the evening celebrity format (*Jay Leno's Tonight*), the issue-oriented format (*Oprah*), and the audience discussion format (*Kilroy*). In respect of the fifth criterion, namely ethical considerations, talk shows fall into two subtypes according to Richardson and Meinhof (1999: 125): exploitative, like *Jerry Springer*, which sacrifice human dignity to media entertainment requirements, and non-exploitative, like *Kilroy*.

Taking into account the changing talk show formats over the last fifteen years, Soulages (2002: 319–320) uses a combination of the first, second, and fourth criteria to distinguish three categories: 'first generation' talk shows (of the 1980s, discussing public issues), reality shows (of the early 1990s, probing into the private sphere), and 'second generation' talk shows (of the late 1990s, confession and confrontation-based).

It is important to note that, although the fundamental characteristics of talk shows are easily recognizable across cultures, it seems possible to identify cultural nuances that distinguish talk shows according to their country of origin. The situational contexts of the British, American, Italian, and French talk shows, for example, differ widely. The parodically conceived British *The Dame Edna Experience* (Tolson, 1991), the American *Tonight Show,* and the Italian *Maurizio Costanzo Show* (Mininni, 1990; Mininni and Annese, 1999) represent quite different realizations of the same, or similar, basic formulas. Intracultural differences are equally important to examine as intercultural ones. The interaction in French cultural talk-shows, such as *Apostrophes*, *Bouillon de culture,* and *Bibliothèque Médicis* follows the tradition of the French *conversation de salon* (Charaudeau, 1991; Charaudeau and Ghiglione, 1999), whereas a typically French hybrid talk show such as *Ciel mon mardi* is a mixture of serious *débat* (political discussions), *reality-show* (accounts of true life experience), and *variétés* (musical performances and jokes) (Mazdon, 1999). To some extent these stylistic differences can be accounted for by deliberate choices operated by the respective broadcasting producers. However, deliberate or not, such choices also concern audience preference and expectations, and thus constitute a revealing perspective on the culture itself.

Methodological Approaches to the Study of Talk Show Discourse

Talk shows have been examined from a variety of perspectives, including cross-disciplinary and cross-cultural approaches. They have recently become the focus of attention in media and cultural studies, as well as feminist studies. A growing number of discourse and conversation analysts are using social interactional perspectives in their studies of talk show interaction.

Scholars such as Mininni (1990), Mininni and Annese (1999), Montgomery (1991), Calsamiglia *et al.*, (1995), Hutchby (1996, 1997), Thornborrow (1997, 2001), Ilie (1998, 1999, 2001), Gregori-Signes (2000a, 2000b), Simon-Vandenbergen (2000), Myers (2001), Honda (2002), and Rama-Martínez (2003) make use of (empirical and/or theoretical) discourse and/or conversation analytical approaches to describe the mediated participant interaction in the co-construction of stories and identity roles, turn-taking strategies, closings, interruptions, personal deixis, non-verbal communication, argumentative functions of question-response sequences, management of disagreement and conflict, and male–female discursive behavior. Tolson (1991, 2001) uses Halliday's (1978) sociolinguistic theory to examine the relationship between talk as performance and the production of identities in broadcasting.

Scholars from the fields of media and cultural studies, as well as feminist studies, such as Carbaugh (1988), Masciarotte (1991), Munson (1993), Abt and Seesholtz (1994), Livingstone and Lunt (1994), Peck (1994, 1996), Krause and Goering (1995), Shattuc (1997, 1999), Mazdon (1999), and Mittell (2003) have often concentrated on the analysis and/or critique of the talk show as a media genre, as a political phenomenon, and on its impact on ordinary viewers. Carbaugh (1988) and Munson (1993) use performance theories as their underlying theoretical framework.

A number of media scholars, such as Priest (1995) and Shattuc (1997) on the one hand, and White (1992, 2002) and Peck (1996) on the other, are particularly concerned with two complementary strategies of the talk show, namely confessional framing and therapeutic framing respectively. Peck's (1994) approach focuses on racism as an important issue in the discourse of many talk shows. Keyes (1999) provides an ethnographic perspective on the theatrically staged role of the studio audience on *Shirley*, a Canadian talk show.

Psychologists, such as Nabi and Hendriks (2003), have concentrated particularly on audience response and reception of talk show messages. Guzman (1996) makes a qualitative analysis of the role of the studio audience in daytime talk shows by applying a theoretical model derived from Berger and Luckmann's (1966) social construction of reality.
